A company of Georgetown men, headed by D. B. Craig, has leased the old Fort Hill placer mine near Georgetown and is making preparations to start work. —The Hume mine, in the Mother Lode belt, is being worked by the Garden Valley Gold Mining Co. An incline shaft has been sunk to a depth of 55 ft. and pay-ore found at 40 ft. A drift is now being run from the 85-ft. point to strike the
MINING

same shoot. Steam-power is used and three shifts are working. J. F. Mullender is manager.—Wingfield and Nixon are operating the Alpine mine and are sinking the incline shaft, which is now below the 400-ft. mark. C. G. Johnson is superintendent.

Nevada County.

(Special Correspondence).—A six-foot vein has been intersected in the adit at the Rose Hill. It is supposed to be the Bromeayadur. The bore has been cleaned up for a distance of 200 ft. At the Champion a north drift from the 600-ft. and a south drift from the 1100-ft. levels are being driven. The company is taking ore from a drift on the 800-ft. level. Several groups of tributers are also working.—The North Star mines have been supplied with more water and the big hoist is again operated by water-power.

The Murchele expects to resume operations this week with about 20 men. The mill will be started as soon as the ore-his are full. Henry Fitter is superintendent.—The new hoist has arrived at the Greystone mine and will be immediately placed. Two shafts are being sunk on promising veins.—The 250-ft. adit at the Le Duc has cut a vein of fair-grade ore. Development is progressing.—Arrangements are being made for the installation of a compressor, 75 hp. motor, and four concentrators at the Central Co. mine. The main adit is in 1400 ft. Several ore veins running from 5 to 14 ft. wide have been intersected by the adit. The adit is being continued to cut the old gravel channel. Twenty stamps will soon be dropping. C. N. Bailey is manager.—Gravel mining above Campovorton promises to be active this winter. The Indian Hill, Brandy City, and Depot Hill companies are constructing restraining barriers across the streams.

Grass Valley, November 9.

Plumas County.

A strike of $20 ore has been made in the Gruss mine near Genesee. A body of $16 ore, four feet wide, has also been opened at another place. It is said that machine drills and compressors will be put in.—The old Crescent mine, near Crescent Mills, is to be re-opened by the heirs of James McDonald. The property has been idle for a number of years because the ownership was invested in an estate.

Sierra County.

John Mayer and Jack Crossman are doing assessment work on their claim in Black’s canyon, a branch of Ladies canyon. They are fixing the ground up preparatory to working next spring.—J. M. Shinna, of the Packer Canyon Mines Co., above Sierra City, has closed the mine for the winter and returned to his home in New York. When he returns in the spring he will continue the main working adit.—The complete material for an aerial tramway has been shipped for the Gray Eagle mine at Gold Point. As soon as it arrives a crew of men will begin its erection and the company hopes to have it in running order before snow flies. A new set of plates have been installed in the mill.

The new wagon-road nine miles long, which connects Campovorton with Snowdon hill, was finished recently, simultaneously with the completion of several extensive surface improvements on the Snowdon Hill drift mine, including the construction of another road seven miles long to the Mountain House, a telephone line to the latter station, a ditch seven miles long, and a number of new buildings at the mine which was formerly known as the Jerry Watts. The buildings are models, up-to-date in its appointments including the superintendent’s residence, boarding-house, dormitory, and store-house. The whole has been accomplished at an outlay of $21,000 and was begun last July. Superintendent L. C. Heller will push the bedrock adit, now in 150 ft., to a point 150 farther on before making a raise to gravel.

Yukon County.

McCornick & Co. and Cotton Bros., owners of the Draper mine, have a small force engaged in cleaning out and remining the main shaft, which had caved in to the first level. It is the intention to get everything in shape and drive a cross-cut to the vein at the 600-ft. level. Richard A. Nichols is superintendent.—At the Ethel, in the Columbia district, several hundred tons of ore are ready for crushing, and it is claimed that all of it will yield more than $20 per ton, besides giving a good percentage of concentrate. Superintendent Richardson is pushing work at all points and expects to have a crushing plant in operation soon.—It has been reported that a company of San Francisco capitalists has been organized to develop the Wheat Rough, near Soulsbyville. This is a property that has at all times been rated as one having a splendid vein of milling ore.—Three men are employed in clearing rubbish from the tunnel of the Over, near Saw Mill Flat. There will follow a thorough re-tilering and then a search for the pocket leads. Charles Peterson is superintendent and owner.—The Birney, at Saw Mill Flat, has been leased by Ray Fulcher and associates, who will begin operations at once. The mine is in the midst of the pocket properties and has produced thousands of dollars.—The Morning Beauty mine, west of the Riverside, has been bought by W. P. Cox, of Robinson Perry, from F. G. Gross and John Beadie.

Colorado.

Clear Creek County.

The Bonnie Brier M. & M. Co. is planning the installation of a 12-hp. hoist on its property in the Alice district. Robert Nimmou, of Cincinnati, is president of the Company and was recently at the property making an inspection.—Operations have been resumed on the Cumberland mine and the shaft is being unwatered. A. V. Dickson is manager.—The Mammoth mine, situated on Brown Mtn., a producer in early days, has been taken under lease by B. J. Charlebon, of Silver Plume, and arrangements are now being perfected for extensive development. A number of capitalists have become interested and funds are promised for extensive operations.—The Big Indian Mining Co., composed of Denver men, has been incorporated and has secured a three years’ lease on the Ajax or Big Indian claim on Leavenworth Mtn. Work is to be started at once.—Jut & glasson, leasing on the upper Frostberg, have uncovered a body of heavy lead ore that measures only two feet wide. The discovery was made where the Paymaster and Mendota veins meet, and indications are that one of the old-time bonanza strikes has been made, for which the Mendota was famous a few years ago.

Gilpin County.

The strike recently made in the Quartz Mill mine in Leavenworth gulch of the Russell district is improving all the time. The shaft is now 429 ft. deep, and is driven to the 500-ft. level before driving is started. The property is owned by the Bezant Gold Mining Co., in which Eastern and Denver people are interested. O. J. Duffield, of Denver, is manager, and J. H. Bawden is superintendent.—The Cherokee M. & R. Co. is operating the Wise Boy property in Lump gulch and has an adit in 125 ft. C. D. Laing, of Gilpin is manager.—Denver people have purchased the Ipa and Popular claims in the Central district and they have arranged for the purchase of a plant of machinery near Eldora, which will be installed as soon as delivered from that camp. The property includes two lode claims and a mill-site. It was owned by Peter Petersen and has produced some fair-grade ore, considering its surface development.—A complete plant of machinery, consisting of an engine, boiler, and air compressor, is to be installed by George Stroehle & Sons at the Smuggler mine of the A. K. R. Gold Mining Co., in Moon gulch. The property has been making an excellent record in production for several months and Manager Ashmore announces that they will add five more stamps to their present milling capacity.

A 10-hp. boiler was delivered to the Hall mine in Russell gulch last week and is now being installed. The property has been taken over by John Stewart, who has given instructions to commence sinking as soon as the plant is in shape.

Gunnison County.

Operations are to be started soon on the Northpole mine, in the Rock Creek district, and continued all winter. Sup-
plies are now being taken to the property. Most of the stock is owned in Boston, Porter Nelson, of Aspen, being the largest Colorado stockholder. — The management of the Mountain King mine is purchasing supplies for the winter's run. When the vein is struck, driving in both directions will be started. A concentrating plant is one of the future improvements planned. — Robert Harper, owner of the Brooklyn properties on Galena Mtn., has stopped work for this season. It is understood that the last work done this season uncovered some good ore which will be developed extensively early next season. The mine is equipped with a steam plant and air-drills.

Teller County.

A company of Iowa men has leased the Four Brothers claim, on Beaver hill at Cripple Creek, and will, it is said, start operations soon. — D. H. Harris and associates, who recently secured a lease on the north 500 ft. of the Moonlight claim on Gold Hill, owned by the Missouri Mining Co. have commenced operations through the Good Will adit. The bore intersects the leading blocks at an approximate depth of 450 ft., and at this depth the lees are driving on a well defined vein. The ore mined at present is low-milling grade, but it is the intention of the management to continue the drift forward to its intersection with a cross-vein exposed in nearby workings, where it is expected a richer body will be entered. — The output made from the properties of the Vindicator Consolidated Gold Mining Co. for October amounted to approximately 2000 tons of graded ore, ranging in value from $10 to $20 per ton, for coarse quartz to $50 per ton for the screening and fine. In addition to the work carried on at the main shaft and elsewhere on Company account, five sets of leesers are producing from the original holdings, with 15 sets of lease operators engaged in the development of the 40 acres acquired from the Independence Con. Gold Mining Co., and better known as the Hull City placer, situated within the town of Independence on Gull Hill. — The output of the Cripple Creek mines for the month of October amounted to $1,467,484 from 63,720 tons of ore. In point of bullion value October was the banner month of the year, but in amount of tonnage the figure is not as large as previous ones. As usual the Golden Cycle heads the list, the gross value of its output being $657,500; the A. S. R. & R. Co. is second with $322,300.

Idaho.

Idaho County.

J. F. Thorp, superintendent of the Buster mine, near Elk City, has returned from Newsome, where he let a contract for 100 ft. of adit on the Mackey mining property, which has been taken under bond by men interested in the Buster mine. The property is one of the most promising in central Idaho. There is a 300-ft. adit which cuts two veins of exceptionally high-grade free-milling ore. Those interested in the bond are F. W. Bradley, J. H. Mackenzie, and Mark L. Requa, of San Francisco. The property is 12 miles from Newsome station, and one and a half miles from the proposed electric railway along the south fork of the Clearwater river. — J. R. Hutchens, manager of the Twin Butte mine, in the Orogrande district, reports that the company will install two mills this winter as auxiliary to the roll-mill now on the property. A recent strike in the mine carries ore that assays over $20, and the output has been assayed for a distance of 2000 ft. and the average assay is a little over $5. — William A. Russell has bought a one-fourth interest in the Simonet placer property, consisting of four claims on Little Elk Creek. The property will be supplied with hydraulic equipment and worked extensively next spring.

Shoshone County.

(Special Correspondence). — Mining throughout the Coeur d’Alene district has been practically at a standstill owing to the election. The county has again gone Republican, more on account of fear of any alteration of the present lead tariff than anything else. The chief feature, however, as far as local industry is concerned, has been the election of Fred Cushing Moore, a Wallace engineer, to the office of State mining inspector by a handsome majority. Mr. Moore is well known throughout the district and it is believed that he will make a worthy successor to Robert N. Bell, whose work has done more for Idaho in this connection than any man who ever held the office. — The Bunker Hill & Sullivan Co. has declared its 13th dividend. This involves the distribution of $75,000 for the month of November and brings up the total disbursed by the Company to $10,550,000, of which $780,000 has been paid this year. The new mill at this property, which will give it a capacity of 2000 tons is now well on toward completion and will mean the employment of practically 1000 men in the mine. In view of this, vast ore reserves have been opened up and new territory entered and explored. On the Sullivan side of the mine extensive orebodies have been tapped, while the recently opened Morgan stopes have exposed an ore shoot that far exceeded the most sanguine hopes of the management. — Ore running as high as 17% copper, $14 in gold, and $3.57 in silver has been found in the property of the Birthday group of claims in the Grand Forks district, owned by W. J. Hornsby. The property has been developed by means of three adits, the last of which has only been driven about 40 ft. The vein has been proved to be six feet wide, of which two feet is of high-grade carbonate ore. — A strike of ore carrying all the way from 1000 to 2000 oz. of silver has been made on the property of the Butte & Coeur d’Alene mine. This ore is gray copper and up to the present time no less than three feet of it has been exposed, in addition to large quantities of milling ore. The strike was made at a distance of 165 ft. from the mouth of the adit. Already several cars are ready for shipment. The ore will be sent to the Panhandle smelter at Ponderay. Some of the ore is practically pure silver and in chunks weighing from two to three pounds. The property has been operated only about one year, but the owners claim that they have already 350 ft. of stopping ground and that by a continuation of the drift they can get a depth of about 1000 ft. A large equipment of machinery has been ordered for the property, including a hoist.

Wallace, November 9.

Missouri.

Jasper County.

(Special Correspondence). — The past fortnight has noted several important strikes in this district. At Knights Station, while drilling a well, ore was found at 115 ft. and 10 ft. of galena was penetrated. At 200 ft. the drill entered the 10th Bub, ore, which continued for 25 ft. The strike is about a mile from the Lone Star and Magnet mines, good producers for some time. — At Purcell, near the Alba camp, a 15-ft. face of coal was recently opened up which is said to be high grade. The run will be further developed. A rich coal deposit has been worked for three years at Alba by Arba Green. The coal is of a better grade than is shipped in from Kamoa. This Alba deposit is being further opened.
up to supply the local trade.—Newman & McKee have been sinking a shaft in West Hollow, in the Joplin camp, and have opened up a deposit of galena and zinc-blenede at 40 ft. carrying a 12-ft. face. A barren flint run was then entered, but the shaft struck a bearing dirt at a lower level. The upper level will be developed as soon as the shaft is completed and the lower run will be further opened when the upper is worked.—Short & Co. have taken over the old Lincoln mine, at Zincite, and after further sinking have discovered a rich run of ore beneath the old drifts. The old workings caved in. Former operations were confined to the upper 120 ft. The vein of ore is three feet wide and some of it will assay 65% zinc.—The management of the Goode mine, north of Webb City, has sunk the two shafts deeper and opened up a richer vein of ore below the old drifts. In the north shaft a larger per cent of galena is being taken out than formerly. A 12-ft. stope is being carried in both shafts. Adjoining the Goode on the west the Robertson mines are opening the same mine. A new shaft is being sunk on the drill-hole, which is down to the 60-ft. level. One shaft is already in the ore and the two will later be connected by drifts.—The Snapping Turtle mine, at Carthage, has been producing for two weeks, the first time in over 20 years. The Turtle shaft is down 60 ft., at which point driving was done in good ore.—The Morning Star producers and owners, in the south-west part of Joplin, is pumping preparatory to re-opening large modern mill on the lease. Considerable difficulty has been experienced by the company with cave-ins. Two serious ones occurred, one undermining the tracks of the electric line and the Frisco railroad. The ground has been strengthened and is now pronounced safe.—Poor Man's gulch, in the northwest part of Joplin, is to be re-opened by Chenoweth, Brown & Swaray. This tract has many shafts, all above the 100-ft. level, where shallow gouges were made for galena in the early days. The new company will lease a portion of the ground and will build a mill at the mouth of the hollow, so that all the ore taken from the tract can be trammed down hill to the mill for treatment. The upper runs will be worked first and the quickest way run in to the lower levels will be exploited later.—Old Jackson Holow southwest of Joplin is being reviled. Matthews Bros. have opened a run of ore from 140 to 150 ft. wide, while former operations were conducted above 100 ft. A mill of 400 tons capacity is to be erected at once. The mill is being removed from a lease owned by these same men in the Duenweg company.—The old ‘forty’ mine of Carterville is to be re-opened by S. Y. Ramage. A 200-ton mill is on the property. The land is known as one of the best producers belonging to the Center Creek Co.—The Highland mine, belonging to the United Zinc Co., in the Duenweg camp, is to resume operations at once. The property closed down a year ago when the panic came and the practically new mill has been operated only a short time. The Company has a shaft into sheet ore at 252 ft. Joplin, November 5.

NEVADA.

ESMERALDA COUNTY.

Three Goldfield leases declared dividends last week, the Consolidated Red Top distributing two cents per share, the Mohawk Jumbo three cents, and the Engineers' lease a total of $130,000. The latter has distributed to date $555,000.—The directors of the Red Top Fraction Mining Co. have decided to resume work about November 15. The shaft is now 350 ft. deep, but the management intends to sink to the 500-ft. level before cross-cutting. James E. Power is president and Frank P. Marisch is engineer. There are six sets of lessees working on the Frances Gold Mountain, at Hornsilver. Ore is being sacked from one lease, and the others have good showings. This property, which is the Royal Flush group, has recently been given the name of the Lost Breyfogle Reclaimed, as some very old implements, including hammers, heavy steel and old copper-headed tamping-sticks have been unseated, along with some specimen ore running as high as $44 per pound.—The Silver Peak Con. M. & S. Co., of Goldfield, has secured a lease on block 7 of the Dayley claim of the Silver King estate, at Horsetiver, and will start work at once. Sinking will be continued in shaft, which is up 310 ft., and the 200-ft. point will be reached as soon as possible, from which level the veins will be prospected. It is the intention of the Company to install a gasoline hoist, perhaps within 60 days.—M. M. Deth and associates have installed a boiler on the Wilson lease on the Grizzly Bear claim of the Junio, at Goldfield. The shaft is now 116 ft. deep. A strike of ore 12 ft. thick was taken down 110 ft. and 2.5 miles west of Tonopah, has caused a small stam-

HUMBOLDT COUNTY.

In pushing work on a lease on the Gee Whiz No. 1, at Chafey, in the vicinity of the Auld Lang Syne, an 8-in. streak of fine galena ore has opened up to 16 in., and the orohody is seemingly Improving with depth. The Gee Whiz is owned by the Utahna Mining & Milling Co., of which H. S. Bixby is the president.—Frank T. Caley & Co., composed of some of the best known Colorado mining men, has secured a lease and bond on the Seven Troughs Buckhorn Mining Co.'s property near the town of Vernon and has commenced a vigorous campaign of development.

LINCOLN COUNTY.

The New Era group, including a 10-stamp mill, east of Searchlight, has been sold to Fred Holland, of New York, by the New Era Mining Co. De Berry & Megede, leasing on the property, having been working a vein, only 8 to 16 in. wide, which outcropped close to a well traveled path between the blacksmith shop and the camp houses, and had been overlooked for nearly ten years. The ore contains free gold and is said to be very rich. The lessees have sold their rights to the new owners.—A high-power pump is being put in at the tenth level of the mine of the Quartette Mining Co., at Searchlight, to enable exploration for the millings operations. Thirty to thirty-five stamps are running, handling 100 tons of ore per day.—The management of the new Santa Barbara smelter announces that it will be in the market for the purchase of ores about the last of November.—The Jupiter C. & C. M. Co. will start work soon. G. Eustice, who is manager, is building a residence on the property which he will occupy. The Alumate Mining Co. is now cross-cutting at the 150-ft. level of its No. 1 shaft, and shaft No. 2 in 65 ft. deep. Two other shafts are down 40 and 25 ft., respectively. Another gasoline hoist has been ordered. Robert T. Hill is now on the ground, giving his personal attention to details.

NYE COUNTY.

The Johnnie M. & M. Co., recently organized by A. D. Myers and T. A. Johnson to work the Johnnie Consolidated mine, has purchased a new 100-ton cruiser, belt-conveyors, and has made numerous minor improvements around the plant. It is thought that within 60 days the mill will be running 100 tons per day.—The Liberty mine, 22 miles north of Tonopah, has started operations. The Cramps, the famous shipbuilders, are the principal owners.—Samuel Newhouse has purchased the Silver Peak-Yanceida property, in the Silver Peak district, and will, it is said, increase the capacity of the mill to 250 tons. M. M. Johnson will have charge of the operations.—Arrangements are being completed to start the mill of the Round Mountain Reduction Co., under new management, by George A. Anderson, of Denver. Some new machinery will be installed, additional water facilities secured, and a re-adjustment of rates made to enable the handling of a larger quantity of ore.—The mines of Tonopah produced, during the week ending November 7, a total of 5218 tons, of an estimated value of $187,025.

NEW MEXICO.

The Vera Cruz Mining Co., operating at Nogal, in Lincoln
county, is installing a 200-ton cyanide plant, to treat the gold and silver ore from its mine on Vera Cruz Mt. The ore is a porphyry-conglomerate and is low-grade. It is mined from adits and open-cuts. L. C. Barlow, manager, states that the plant will be operating in 60 days. The new concentrator of the Ocean Wave Mining Co. will be started up about the middle of November. The company has been shipping only first-class ore heretofore, and has built the mill to treat the accumulation of concentrating ore. Robert Linton is general manager. The mine is at Hernosa, Sierra county.

CANADA.

BRITISH COLUMBIA.

The Dominion Copper Co., of New York, is in court at Grand Forks for permission to borrow $20,000 for the purpose of protecting its property during the process of reorganization. P. F. Rossa, general manager, who was recently appointed receiver and later provisional liquidator, is seeking this additional power from the court. The assets are far in excess of its liabilities, the properties being estimated to be worth $2,000,000, but the company is in need of the ready cash. The trustee for the bondholders is the National Trust Co., of Toronto. The money is to pay off the men, and also to retain a few men to keep the water out of the mine until the new company takes charge.

John Keough, of Colville, Wash., announces that a concentrator, crusher, and other machinery will be installed on the Keough property in the Colville district, 12 miles north-east of Boundary. An arrastre was installed last spring, but did not prove satisfactory in saving galena and telluride ores. While the quartz in the vein is not of great width, the slate surrounding carries gold enough to be payable. The boiler and compressor plant of the Dominion Copper Co.'s Stemwinder mine were shipped to Mayie last week, having been sold to the owners of the Aznaca mine, in which property it will be installed. The Dominion's new air-compressor is sufficient to supply all the properties here.

H. Lewiston, manager of the Queen mine on Sheep creek, recently took to Nelson a gold brick valued at $7000, the result of the clean-up of the free-milling ore of the mine. The output of the mine has been increased from 155 to 400 tons per week by doubling the number of stamps in the mill.

FOLLOWING is the ore tonnage shipped from and crushed at the mines of Rossland for the week ending October 31: Centro Star, 3530; Le Rol, 125; Le Rol No. 2, 350; St. Elmo, 55; I X L, 3; total, 6192 tons.

YUKON TERRITORY.

Henderson and Follies have recently returned to Dawson from a prospecting trip up the McMillian river, a tributary of the Pelley. They say that while they found gold in almost every creek, the country is not attractive for hydraulic mining because there are too many large boulders.

The Davison dredge, near the mouth of Forty-Mile creek, has closed for the season, and Frank Davison, manager, and Billy Moore, dredge-mounter, have arrived in Dawson. The dredge has had a successful season and the company is planning to ship one or more dredges to the Forty-Mile next season. The Davison dredges will have the advantage of being able to float from Whitehorse down the Yukon and up the Forty-Mile direct to the ground on which they are to be worked.

MEXICO.

CHIHUAHUA.

(Special Correspondence).—The property of the Rio Tinto Copper Co., at Terrazas, formerly owned by Juan Creel and associates, has passed to the control of Corrigan, McKinney & Co., of Cleveland, Ohio, who already owned the San Rafael mine and have since added the Columbia to their holdings. Since acquiring these properties the company has placed R. R. Hutchinson in charge as manager and commenced mining operations. In the meantime a new 200-ton copper furnace, 42 by 192 ft., with 12 tuyeres on each side, has been installed at the old plant and other equipment put in order, and it is announced that the furnace will be blown in by December 15. The intention is to take in some custom ore to add to the output of their own mines. The main part of this district consists of a copper zone in a limestone country, with a body of greenstone which has come up through lime. The copper ore, comprising oxide and carbonate, occurs in irregular deposits on the crest of the orebody and greenstone the mineralization extending into both, and along the strike of the contact. In some places the ore is entirely in the greenstone. The main orebody is said to extend 600 metres in length and to have a width of 3 to 40 ft. The ore runs 4 to 41½% copper and contains 2½% silver and 25c. gold. There are porphyry dikes running through this lime country, in one of which is a body of iron sulphide which has been well opened. This will make the requisite smelting mixture. This sulphide carries one-half per cent iron. Farther to the northwest is a parallel lead belt, partly developed, showing both galena and lead carbonate. Between the smelter site and the main mine workings is a low mountain ridge, through which a 1400-ft. tunnel has been driven, and a 36-in. gauge railroad has been extended from the smelter through this tunnel to the several shafts, making a mile of track. There are seven shafts, one having a steam hoist and the others gasoline hoists, the San Rafael, San Martin, and Columbia being the principal ones. The San Rafael is 440 ft. deep, and from it a cross-cut has been driven 1000 ft. southerly to cut the ore in the main body. Mr. Hutchinson was formerly of the Conchino mine, west of Mina, and H. J. Schneider, smelter superintendent, and M. D. Murray, mine superintendent, were connected with the Rio Tinto under David Goodale's management. Felix McDonald, who owned and sold several of the properties in Terrazas district, still has important holdings here. His American mine is under option to T. N. Baraschull, of Pittsburg, who has invested heavily in Atlanta, Idaho, and in Pinos Altos, in western Chihuahua. This American is a lead mine, having some silver and gold. It lies farther northeast and is on a belt parallel to the Rio Tinto. Mr. McDonald thinks work will be resumed on the Americano next year.

Terrazas, November 5.
Special Correspondence.

SALT LAKE, UTAH.

Important Improvement in Fume Condensation. — Neutralizing Sulphur Gases. — Details of Method. — New Converter Roaster. — Sintering the Ore.

The United States Smelting, Mining & Refining Co. has just made public announcement of the perfection of its process for elimination of injurious fume from its smelter gases. Experiments have been in progress at the smelting works of the company at Bingham Junction since the relative advantage of the plan has been realized, and the perfection of the process is now announced. The object of the new process is to divide the dust, and, by the use of coke, to increase its temperature up to a point sufficient to make it suitable for sintering.

The process is conducted in a bag-house, into which the gases are forced after passing through three series of steel tubes from one brick chamber to another, 10 tubes, each 2 ft. diam. and 20 ft. long, leading from one chamber to the next. Finally the gases are condensed through a steel tube 6 ft. diam. and 20 ft. long, and, after condensation, the resulting liquid is collected by means of a wooden bowl in the bag-house. The reaction takes place in the flies, while the fumes are passing to the bag-house, at a temperature between 100 and 110° C. The gases entering the bag-house are of about 300° C. are cooled in transit by passing through three series of steel tubes from one brick chamber to another, 10 tubes, each 2 ft. diam. and 20 ft. long, leading from one chamber to the next. Finally the gases are condensed through a steel tube 6 ft. diam. and 20 ft. long. This cooling is effected by radiation of heat through steel sheet, added by the evaporation of water trickling upon the first two series of tubes. The tubes are forced into the bag-house under induced draft by means of a 100-hp, electrically driven fan. The zinc oxide is produced from crude zinc sulphide, concentrate, and other material, the composition of which the company does not now desire to divulge. The mixture is dampened, and in turn fed upon the grates of a battery of small furnaces, constructed like a fire-box about 6 ft. long by 3 ft. wide. Five fire-boxes, or 'zinc furnaces,' as they are called, with party walls, constitute the plant. The mixture as fed upon the grates is maintained at a thickness of nearly 12 in. Each furnace will treat 5 tons of charge per day. In the event that material is lacking for these furnaces, commercial zinc oxide, mixed with other ingredients of unstated composition, is fed to the flue-gases at the fan, by an automatic feeder. The bag-house contains 2500 bags, 18 in. diam. by 33 ft. long, which are shaken twice in each 24 hours, the dust falling into a 'cellar,' where it is burned before being drawn from the hopper-boxes into the bag-house. Five tons of dust are produced per day.

As an addition to the bag-house, sufficient for 1250 bags. is now being built. Cotton bags are employed for the blast-furnace gases, but woolen bags are necessary for the gases from the roasting plant. The roasters are of the old fashioned reverberatory type, operated by hand. There are six of these, each 70 ft. long, only two being fired at present.

In addition to the hand-roasters, the company has developed a system of 'converter-roasters,' within the last four months, which has given such favorable results that a battery of 6 has been installed, and is in operation. This, in effect, is a sintering furnace, adapted to raw ores. Each 'converter' consists of a brick-lined square shell, 6 by 6 ft. in horizontal section, and 3 ft. deep, with a hood 3 ft. high. The bottom consists of closely set grate-bars, through which the blast under pressure is delivered to the furnace. To start the charge burning a 'primer,' consisting of a mixture of coal and raw concentrate from an iron pyrite ore, previously ignited in a separate furnace constructed similarly to the 'converters,' is spread to a thickness of two inches upon the grate; the ore-mixture is then spread upon this, 2 or 3 in. at a time. Each layer is allowed to ignite before the next layer is added. The full charge is 8 tons, and the time required for sintering is from 10 to 12 hours. It sinters to a solid cake, which is forced out upon a steel 'boat' by means of a ram, in the same manner as coke is discharged from a by-product oven. A travelling crane then lifts the cake, trips it, and allows it to drop upon a steel floor. If this does not succeed in breaking it sufficiently, a large pear-shaped cast-iron weight is lifted and dropped upon it. The fragments are then further broken by a Blake crusher, and the crushed product is conveyed automatically to steel cars, which deliver it to steel bins in the furnace-house, where it is mixed with the charge for the blast furnaces.

As before stated, the function of these 'converter-roasters' is to sinter the ore, rather than to desulphurize. The elimination of sulphur from any charge in a sintering furnace is necessarily imperfect, although an important loss of sulphur occurs. The charge for the 'converter-roasters' is made up so as to contain 33% SiO₂, with a sufficient quantity of iron to insure ready fusibility. No lime is added, but the charge here used contains lime to the extent of about 5%. The lead in the charge varies from 20 to 25%. The manager claims that this new sintering system is superior in point of efficiency and economy to any pot-roasting or sintering process hitherto developed. The company is also installing an arsenic plant, consisting of a Brunton furnace with a series of brick condensing-chambers for the crude arsenic, and a reverberatory refining-furnace, with its corresponding brick condensing-chambers, for the white arsenic. It is expected to produce a commercial grade of arsenic that will compete with the imported brands.

Mining conditions at Park City are much better than for more than a year past, and the prospects of a greater output of ore during 1908 are bright. The big companies, which had their operations handicapped by the drying of the Ontario drain adit, are now in full force. An instance of this is the Daly West, which is driving for its orebodies in a drift from the Ontario adit. This drift lies across the Daly-West boundary line about 300 ft. and will reach the main body in about 700 ft. more and at a depth of about
LONDON.

Chemical Manufactures. — Electrolytic Alkali Co. and Its Products.—

Mineral Production of Britain.—San Miguel Copper Mines.—Oil Process Litigation.

From time to time I have referred in this column to the various firms of chemical manufacturers in England and have given particulars relating to the United Alkali Co., Brunner Mond & Co., and the Castner-Kellner Alkali Co. This week I am able to give some information about the British Alkali Co. which works the Haregrove-Bird patents at Middlewick, Cheshire. This Company has had a somewhat checkered career so far, and it has not yet won the financial success that it desires. Your readers are probably not familiar with the electrolytic process used by this Company for the production of chlorine and soda direct from the brine from the wells. Briefly, the anodes are gas carbon and the cathodes consist of copper gauze, and the mixture is placed in a diaphragm cell. The virtue of the process depends chiefly on the composition of this diaphragm; and naturally its exact nature and the method of making it are not disclosed. It consists of a mixture of mineral substances and is not porous under ordinary conditions. It is a hard smooth plate and presumably acts by osmosis. The cathode chamber outside the copper gauze contains an atmosphere of carbonic acid and steam, and the resulting liquor consists of a solution of carbonate of soda. The soda crystals and bleaching powder produced are of the highest quality and the bleaching powder has the advantage of not being hygroscopic, a fault possessed by the product obtained in the Leblanc process, where there is always a certain amount of hydrochloric acid present in the chlorine to form calcium chloride with the lime. Owning to the absence of this, it is impossible to obtain any better price than the average for these superior products. In many cases soda and bleaching powder are sold by the big chemical manufacturers as mere by-products for sale to be made use of by the others for other purposes. The Electrolytic Alkali Co. suffers from this. It does not manufacture anything but what may be called staple products. The only variation is that in some cases bicarbonate and hydrate are made instead of soda crystals. Consequently it is at the mercy of such great organizations as the United Alkali and Brunner Mond, not to mention the German firms whose products enter England duty-free. In the early days of the Company, everything was wrong, because the directors, managers, and patentees knew nothing about costs. It is only during the last two years since Mr. Irwin took up the management that business-like methods of chemical engineering were introduced. At the present time the most modern methods are being used for the generation of the electric current, and the Company now has the advantage of owning the brine-wells in the land on which the works are situated.

A few weeks ago I gave some information in this column with regard to the number of people employed in mining in Great Britain. This week the statistics of production during 1907 have been published. As might be expected, coal formed by far the most important item, for the value at the pit's mouth was £120,527,378, out of a total of £355,279,085, the value of the total mineral production. The output of coal was the largest hitherto recorded, being 16,763,334 tons greater than in 1906. The total export of coal was 5,183,276 tons, which consisted of 2,968,501 tons of coke and patent coal, 1,618,316 tons supplied for the use of steamers leaving British ports, and 6,600,947 tons of coal sold to foreign buyers. The amount of coal remaining for home consumption was 183,645,596 tons, of which 21,116,547 tons were used in iron smelting. Of the metallic minerals raised during 1907, iron ore was by far the most important, the output being 15,721,694 tons valued at £1,433,415. This ore yielded 5,126,949 tons of iron, which is over one-half of the total quantity of pig iron made in this country. The output of tin ore was 7,080 tons of concentrate, containing 4467 tons of metal. The output of dressed zinc ore was 29,082 tons containing 7608 tons of metal. Dressed lead ore to the amount of 22,593 tons containing 24,460 tons of metal, and copper ore amounting to 6525 tons containing 666 tons of metal were produced. With the exception of iron and lead ores the production showed a slight decrease. The production of bauxite was 7537 tons, but no information is given relating to the amount of aluminum extracted. The amount of gold produced in 1907 was 1884.3 troy ounces. It is to be seen that the metals other than iron and tin play a small part in the mineral wealth of the British Isles.

Reference was made a few months ago to the drastic alterations in the direction and management of the San Miguel copper mines in the south of Spain. The new controllers found that the finance was in a state of chaos and that the method of accounting was a diaphragm cell. Feeling the accounts and restoring order generally it has been found necessary to raise additional capital in order to make the company solvent. The present debts of the company amount to £150,000, a large part of which is owing to the bank. The directors now propose to increase the capital from £150,000 to £300,000 and issue the new shares together with 9998 of the 129,000 shares not already taken up. In this way about £50,000 will be provided. I have the pleasure of recording that all these shares have been placed, a sufficiently remarkable event in these days of continued depression.

In your issue of August 22, I gave some information about the litigation between the rival flotation processes, that is, between the Elmore and the Sulman-Picard-Ballot group. I mentioned that there were three suits pending. Two are actions over patents, the two parties being alternately plaintiff and defendant. The third is an action relating to an agreement between Messrs. Ballot, Webster, and Hay, made in 1888, when Mr. Ballot and his friends were thinking of taking up the Australian patents of the old Elmore oil flotation process. As is usual when patentees let other people into their works, there was in this case an agreement made whereby all improvements discovered by Mr. Ballot and his chemists should belong to the Elmore. Subsequently Mr. Ballot decided not to acquire the patents, but instead acquired the Cattermole and other patents and introduced improvements which were patented by him in conjunction with Sulman & Picard, the chemists who had conducted the investigations at the Elmore works. The Elmore claimed that these improvements were not improvements made by the Cattermole and other patents and that they were not improvements made by that company. This case has now been brought before the courts. After going forward this week for some days, the judge, Justice Parker, drew attention to a point of law, which, curiously enough, had not occurred to the eminent array of counsel engaged by the two sides. He threw out the hint that Mr. Ballot had not acquired the Cattermole and subsequent improvements for himself and his co-owner, Mr. Wills & Hay, but as trustee for the company known as the Minerals Separation Syndicate. It seems remarkable that people can assume so many different capacities, but the lawyers present could not contest the correctness of the Judge's view. The case therefore came to a sudden termination.
MEXICO.

Increased Production of Ore in Chihuahua. — New Productive Mines.

— Oil Competition. — Rio Plaza.

In September I made note in these letters of the material improvement in mining conditions about Chihuahua, and of the increased shipments of ore from that point during August over and above June and July of this year. September showed no marked difference in production from that of August, but the October output far exceeded that of some 3000 tons more than that of August, or a total of 18,750 metric tons. The greater portion of this increase in production came from Santa Eulalia, some of the producers in that camp having added to their August tonnage by over 50%, and the grade, too, has had to be brought up to meet the lower metal markets. The outlying districts have also added their increased quota to swell the whole, due largely to improved transportation with the passing of the rainy season, but also to the good results of intelligent development work throughout the region about Chihuahua. It is only the immense orebodies at Santa Eulalia and the remarkable richness of the ore from other districts that has made this possible during the continually declining metal markets. One of the most important of these new producers is the San Francisco, of J. S. Qualey, at Yoyuvor, a short distance west of Pinos Altos; from this mine a high-grade gold and silver ore is being shipped to the American Smelting & Refining Co., netting $600 per ton for the first-class and $300 for the second-class, while the milling ore running about $60 is being stored. Mr. Qualey has an option on this property from the owner, Gov. Enrique C. Creel. At Pinos Altos nothing is being done by the Company, but the lesser ore, on the upper levels, is being dumped into the mill, with getting in shape to work them in an energetic and systematic manner, and before the end of the year will be obtaining results. In Uruacueb T. A. Ripperdan is sinking on a rich ore running well in gold, silver, lead, and copper in the San Timoteo, and is now obtaining bids for a mill for the proper treatment of the ore; and the Watterson Gold Mining Co., near by is rapidly completing its new mill. At Sahaypanca the Sahaypanca Mining Co., which has been re-organized as the Pennsylvania-Mexico Mining Co., with $1,000,000 gold capital, still under the management of George E. Howard, is preparing to resume operations, and Pittsburg people have taken an option at $250,000 on the adjoining Santa Teresa mine and mill, where development work will be resumed, also under the charge of Mr. Howard. East of Chihuahua near Anguayillo, the Chihuahua Copper Co. is shipping from two to three cars per week of high grade concentrate to the Aguaesalientes plant of the American Smelting & Refining Co.; The Mexican Midland Co., of D. M. Evans, is opening up a splendid looking body of lead carbonate; work has been resumed on the Mano Negra of M. F. Guerrero, near San Sebastian, and an army of people have had their engineer making an examination of the Las Vinas copper property of G. E. Voorhees, Jr., also near San Sustenes, which has been idle since the drop in copper last year. In the Santa Barbara district, near Parral, the experiments of the Minerals Separation Co., using the Sutton-Steele dry table, seem to have proved a complete failure in the treatment of the complex sulphide ores of the San Francisco del Oro mine, of which there are immense bodies, and the Company now contemplates re-organization with $375,000 capital to raise funds for further investigations, while continuing shipments of the clean lead sulphide ore.

The threatened oil war which was mentioned in these letters several months ago seems to be under way in Mexico City, the Waters-Pierce Oil Co. meeting every cut made by the new company of A. Pearson & Son. Clay Arthur Pierce, president of Waters-Pierce, is at present in Mexico looking after the Company’s affairs. The gusher of A. Pearson & Son at Dos Bocas, in the State of Vera Cruz, which exploded and caught fire on July 4, and spouted fire for three months, continues to flow at the rate of about 12,000 bbl, of oil per day together with great quantities of salt water, the oil being stored in immense surface reservoirs while the water is drained into the Gulf of Mexico. The rapidly increasing production of oil in Mexico is leading to its extended use as fuel on the railroads, and a number of industrial enterprises, among which is the American Smelting & Refining Co., are experimenting with it for boiler purposes.

The Rio Plata Mining Co. has been operating about a year and its property has yielded a net return of $29,000 per month for the past ten months. The mine is situated in the Sierra Madre, in southwestern Chihuahua, on the Rio Setentrition, which flows to the Pacific. It is reached by an 85-mile trail from Sanchez station on the Kansas City, Mexico & Orient railway. The mine is developed by 2500 ft. of work on a vein that has an average width of 4½ ft., having a dip of 73° and cutting through a mountain spur of diorite. There are six adit-levels on the vein, entering from the mountain side that overlooks the river. There is a vertical distance of 515 ft. between the highest and lowest of these levels. The ore consists of quartz, carrying silver as sulphide, bromide, and metallic, associated with iron sulphide. Some well defined slabs of silver sulphide and native silver have been found next to one of the vein-walls. A shipment of 15 tons of ore was made that yielded 550 oz. silver per ton. This, of course, was selected and sorted from the highest grade in the mine. A 25-stamp mill, operated by water-power, is situated on the river and a 1460-ft. tramway conveys the ore from the mine to the mill. The latter is equipped with stampers, Card tables, Wheeler pans, Pachuca tanks, and Moore filters. An electric plant, with a generator run by water-power, is under construction. The Rio Plata is a New York company, of which Henry W. Miller is president, with D. W. Shanks, of Chihuahua, as general manager. Mr. Shanks has directed operations and constructions from the start and has had some strenuous experience in transporting heavy equipment by pack animals a long distance and getting it installed in double-quick time.

John Breckinridge, manager for the Illinois-Jalisco Mining Co., was shot by Carlos Madrid at Aljufia on October 23. He was wounded in the abdomen, and died on October 29. The Certuchena mines, in Tepic, have been purchased for $50,000 by a syndicate headed by M. F. Wright, who is said to represent Genes Randolph, of the Southern Pacific Railway. The Certuchena mines have been owned for many years by Lonergan and Stanhope, two Englishmen. J. P. Casey is to be manager, for the new company. The Magistr and Las Moras copper mines, in the Ameca district of Jalisco, have been bonded to James P. Harvey, Patsy Clark, and
and others, for $180,000. The company owning these properties was organized by L. H. Taylor, Jr., of Philadelphia. A good deal of exploratory work has been done this year, under the direction of Mr. Harvey.

The San Toy Mining Co. is shipping 100 to 120 tons of ore daily from its Galdeana and Juarez mines, in Santa Eulalia district, the greater part of it coming from the latter. The ore runs 5% lead, 20 to 40 oz. silver, and 15 to 22% sulfide. The lead and silver are as a carbonate and the silver as a chlorite. The orobodies are continuous for over a mile, striking through the limestone of the district, and is contiguous to a well defined fissure which for the most part contains barren material. While the ore-zone has a definite strike along this fissure, it does not occur as a vein, but as a deposit of irregular width in the line, and has a dip of 15° which carries on down to that of the bedding planes. Its width ranges from 10 to 200 ft., the gangue being an altered line. The limestone of the district, in which the orobodies occur, is overlaid by a rhyolite cap, which on this group is 250 to 400 ft. thick. The Galdeana shaft is 1170 ft. deep, cutting one ore deposit at 400 ft, and another at 1100 ft. The Juarez shaft is down 564 ft., with its main level at 464 ft. The working forces consists of 200 men at the Juarez and 50 at the Galdeana. Development to the extent of 12,000 ft. per month is being done. A 3400-ft. aerial tramway, with wood towers, carries the Juarez ore from that mine to the Galdeana terminal of the main four-mile tramway, having steel towers. The latter conveys the ore to the bins at the San Toy railroad that connects with the Mexican Central. On the operating force are W. N. Pink, general superintendent; C. P. Holter, superintendent of the Juarez mine; H. J. Lynch, foreman of the Galdeana. Donald B. Gillies, president of the company, is inspecting the property at this writing.

**BUTTE, MONTANA.**

**Butte & Superior Lawsuit.—Raven Affairs.—Development of the Big Mines.—Productive Area.**

The Butte & Superior Co. has won its suit against John McAlpine, a wealthy lumberman of Dubuque, whom the company was compelled to sue to get payment of $5200 due on a note given for a stock subscription. McAlpine, who claims that he was induced to subscribe through misrepresentation as to the value of the company's property in the Butte district, declares that he will fight the case to a finish, and will therefore move for a new trial and then appeal. The trial has been bitterly fought, for to lose the suit meant that every share of stock held by McAlpine lead and sue to recover money paid to the company. According to reports, there was some astonishing testimony given on both sides of the case. The Butte & Superior ground lies outside the copper-producing portion of the district, but its prospects are good. There has been a great deal of published misrepresentation as to the value of the property, but the chief grievance of McAlpine probably lies in the fact that he paid $4 per share for his stock, and it is now selling below $1, which is all it is worth on the present showing of the mine.

A report of the Raven Mining Co. contains information that must have been known to most of the stockholders, namely, that the company has not been successful in developing a mine. The report covers a period from June 1, 1904, to September 30, 1908. Previous to the first date the company had been idle for a year and a half, following the sensational rise in the price of Raven stock to $8, the closing of the property through the action of the Amalgamated, and the drop of the stock to 50c. per share. In order to reopen the Raven mine a lot of re-reefering in the shaft had to be done, and a number of caves had to be taken up. The stock was then sunk from 750 to 1290 ft. A larger holding engine has been installed, and to that of the Ravensberg workings erected. About 9000 ft. of openings have been made, in drifts, cross-cuts, shaft, and winzes. The work exhausted the funds of the company, and it is reported that recently one of the large stockholders in the East took 30,000 shares more of treasury stock at $1 per share, the par value, without commission, thus providing temporary relief. It is expected that with this sum the shaft can be sunk an additional 300 ft. In the upper levels of the mine lessees have been at work on the silver-gold ores and have paid the company several thousand dollars in royalties. This work has been of particular value, in that it did development at a profit, instead of an expense. According to the report of the general manager, the vein cut on the 900-ft. level at 200-ft. grade and strikes with low-grade ore.

The Amalgamated, North Butte, and Coalition mines are being kept several years ahead of mining by development work, and more than a ton of ore is placed in reserve for every ton mined. Every property of the Amalgamated, with the exception of the mines of the Parrot and Trenton companies, has developed wonderfully during the past few years. A great amount of work of an exploratory character is now going on in the Parrot and Trenton mines, with the hope of opening new orobodies. The Trenton, which is working the Gagom mine, recently finished sinking the shaft several hundred feet deeper, and is now cross-cutting at the 2200-ft. level for the purpose of opening the veins. The Gagom was a silver producer in years gone-by, but ever since the Amalgamated has controlled it, this mine has been disappointing. The Gagom vein seems to pinch out as it strikes north and the workings of the other mines are the farthest west of any producing mine in the Butte district. The farther west the workings have been extended the poorer and smaller the vein has been found. On the east side of the Anaconda hill the veins are broken and faulted, and on the west side the veins seem to pinch out to nothing, so that as far as present developments have disclosed, the big copper deposits are practically confined to the hill. However, the hill mines themselves, instead of showing any evidence of diminishing value, are yearly getting better, and the deeper the veins have been the richer they have been found. This is true of the Anaconda, High Ore, Bell, Diamond, Nevernest, Mountain Consolidated, Buffalo, St. Lawrence, J. I. C., and Gallatin mines of the Anaconda Co.; of the Pennsylvania, Mountain View, Leonard, East and West Colusa, and other operated mines of the Boston & Montana, and it is hoped to prove true of the Parrot, in which the Amalgamated Co. is cross-cutting to open the veins at the 1900 and 2000-ft. levels. The vein on the 1900 should be reached in another week or two. John Gillie, the manager, says he has no doubt that ore will be found in the vein on that level; in fact, it has been reported among miners that the vein has already been reached, but the general manager denies it. It is stated the cost of producing copper on the Butte now does not exceed 10c. per lb. in any profitable mine.

Butte stockholders of the Snowstorm Mining Co. have received notice of a dividend of 3c. per share, payable October 29, to stock of record October 10. The last previous dividend was paid a year ago. The Company is capitalized for 1,500,000 shares and has distributed in dividends to date $540,000. The Greenough Eros, the chief stockholders, have been operating the property as a sort of family affair. Mining men generally consider the Snowstorm as a big copper property with wonderful possibilities. The Butte Steadfast Copper Mining Co. is developing a property north of Butte and is driving an adit with the object of opening a vein at a depth of 200 ft. It expects to reach the vein about the middle of November. It is reported that the new Boston and Forge prospect is developed and good ore in the property it is developing at Corbin, adjoining the claims of the Boston & Corbin Co. The claim is being developed by adit, which is now 400 ft. long. A strike in the Copper Eagle mine in the north Butte section was made in the shaft at a depth of 350 ft. and it is claimed that 2 ft. of the ore will assay 400 oz. in silver, while a streak assay 1000 ft. of Boston Mining Co. has struck good ore in the property. The only work now in progress in the once active Butte & Encorn district, north of Butte, is being done by the North Butte Mountain Co., which is engaged in sinking a shaft on the J. I. C. claim.
The local stock market has lately been characterized by great activity in Cobalt stock, and a steady upward tendency, extending to almost the entire list, stimulated by large buying orders from abroad. A noticeable feature of the present boom is the greater discrimination shown by the purchasing public, as evidenced by the demand for dividend-paying stocks or those of actually producing mines, as compared with shares of a merely speculative character. Another feature indicating that the market is getting on a sounder basis is that in the new flotations the capitalizations are generally low. The continued appreciation of the principal issues is apparently justified by the conditions of the mining industry, the increase in the volume of shipments, and the new discoveries, which are almost of daily occurrence.

The Red Rock mine, which has been inactive for some time, has been sold to F. B. Chapin for $26,100. The new owner has put a force of 25 men to work on the property, three-fourths of which has never been stripped. The shaft will be sunk for 100 ft. farther and a boiler and air-compressor installed. The Silver Leaf has cancelled the agreement under which the mine was worked by H. G. Symonds, and has engaged George Leyson, formerly of the Silver Queen, as manager, with Stuart H. Thorne as assistant.

Important finds have been made on the Temiskaming, where vein No. 2 has widened to 43 in. of high-grade ore composed of silver sulphides, native silver, and smaltite. In cutting a station in the shaft at the 100-ft. level a new 12-in. vein was struck, a few feet from the shaft, carrying over 45 oz. silver per ton. The Chambers-Fairland recently struck the La Rose vein at a depth of 55 ft., showing ore identical with that of the latter company, namely, cobalt, smaltite, and niccolite with much native silver. At the Cobalt Central a find has been made at a depth of 185 ft. by diamond-drilling the vein, which is 20 in. wide, of smaltite, native and ruby silver, paralleling the main vein. The Coniagas is increasing the capacity of its concentrating plant to 30 stamps, which it is expected will be in operation by December 1, making the daily capacity of the mill 130 tons. At the first level preparations are being made to stop, so as to keep the mill going. A new shaft is being sunk on the Fourth of July Nipissing vein on the Coniagas. It is down 50 ft. and will be continued to 120 ft. to connect with No. 2 level of the Coniagas workings. The Temiskaming & Hudson Bay has picked up the new vein found on the Little Nipissing, which must extend across the Right of Way property, and has also struck a new vein varying from 6 to 18 in. wide and well mineralized. The Gifford Cobalt Mines is a new flotation, capitalized at $150,000, to work a well-known property adjoining the Temiskaming. The shares, which were put at 25c. each, were rapidly sold.

The Ontario Government has undertaken the construction of a wagon-road to open up the new mining regions lying to the northwest of Cobalt. It will run from Earlton, a point on the Temiskaming & Northern Ontario railway 25 miles north of Cobalt, westward for 49 miles through Elk City, across the Montreal river, terminating at the northern end of Gowganda lake. A large number of claims have been taken on the Elk Lake, admiraliteite, taking the place of the Earlton and Dowd, and a road is being pushed through the immediate neighborhood, but the inaccessibility of the region has greatly retarded development work. It is hoped that the road will be completed by next spring. The town of Elk Lake, on the Montreal river, about half-way between Earlton and Gowganda lake, has this season developed as a trading centre and source of supplies for mining parties. Prospecting has been going on all the summer and fall, and many sales of properties at good prices have been made. Development work is being actively carried on at the Otisse, Moose Horn, Blackburn, Cartwright, Craig, and other properties, and many discoveries have been reported. At the Bonsall locations, comprising 320 acres between Miller and Everett lakes, seven veins have been found, the largest showing 7 in. of ore, and 15 bags of high-grade ore are ready for shipment. George Glendenning, well known in connection with the University mine, Cobalt, is one of the syndicate that has undertaken the development of the Bonsall properties.

Willet G. Miller, Provincial Geologist of Ontario, has gone to inspect some of the new silver-bearing regions surrounding the Cobalt area. A statement published by the Provincial Bureau of Mines gives the value of the output of the metaliferous mines and works of Ontario for the six months ending June 30, at $8,083,264, the details being as follows: Arsenic, 256 tons, value $1,573; cobalt, 365 tons, value $29,822; gold, 1524 oz, value $7,672; silver, 7,746,557 oz, value $2,888,091; copper, 3857 tons, value $517,417; nickel, 4779 tons, value $322,828; iron ore, 8,440 tons, value $214,284; iron pyrites, 8728 tons, value $27,968; pig iron, 184,355 tons, value $2,401,708. The Larder Lake Proprietary Goldfields, Ltd., is being wound up, the court having issued an order to that effect upon the application of creditors. It was one of the most prominent of a number of wild-cat concerns with big capitalizations which took advantage of the fact that some real gold existed at Larder Lake to exploit the over-credulous public. It had a $3,000,000 capitalization, collected some $150,000 in real money, worked the property for a few months, and stopped operations a year ago for want of funds. The applicants state that not over $50,000 of the money received was laid in actual development. They charge the directors with misappropriation of the funds and ask for an investigation. They will probably get it, but what good it will do anybody is not very clear. There have been 'investigations' in plenty in connection with similar swindles, but there it has ended. The Highland Mary promoters are still at large.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Cross-cutting is the term used in Alaska to describe the drilling of a series of holes across a creek.

Deviation in diamond-drilling has been known to be as much as 2185 ft. in a depth of 4802 feet.

A good ‘dope’ for protection against mosquito bites is citronella, an oil distilled from lemon peel.

Citizenship of the stockholders of an American corporation need not be proved, and issue cannot be taken on this point.

The capacity of a circular tank in U. S. gallons (231 cu. in.) is \( d^2 \times h \times 0.0034 \), in which \( d \) and \( h \) are the diameter and height, respectively, of the tank in inches.

Miners feel the effects of moist heat when the wet-bulb thermometer registers 75° F., and it becomes necessary to strip, so as to expose a greater surface for evaporation.

A contract between mine and smelter for the purchase of ore has been repeatedly held to be non-assignable, as the mine contracts for the skill and integrity of that particular smelter.

The act of naturalization is retroactive, so that if an alien has located a claim and afterward becomes, or declares his intention to become, naturalized, his location is good from its original date.

Alcohol can be used with more or less success in stationary and marine gasoline engines, and these gasoline engines will use from one and one-half to two times as much alcohol as gasoline when operating under the same conditions. The possibilities, however, of altering the ordinary gasoline engines as required to obtain the best economy with alcohol are limited; for the amount that the compression can be raised without entirely re-designing the cylinder-head and valve arrangement is ordinarily not sufficient, nor are gasoline engines usually built heavy enough to stand the maximum explosive pressures with alcohol, which often reach 600 and 700 lb. per sq. in. With the increase in weight for the same sized engine designed to use alcohol instead of gasoline, comes an increase in maximum horse-power of a little over 35%, so that its weight per horse-power need not be greater than that of the gasoline engine, and probably will be less.

Pure carbide will yield from 5.5 to 5.8 cu. ft. of acetylene per pound, but chemical purity is not practically possible from an economic standpoint. Between 4.25 and 4.75 cu. ft. is the average efficient yield when used in a good generator. The relative quantities, by weight, of water and carbide necessary to form acetylene and dry slaked lime are 36 parts of water and 64 parts of carbide, which yield 26 parts of acetylene and 74 parts of slaked lime. Water will, therefore, theoretically decompose nearly twice its weight of carbide, but in practice, in a good generator, about 17 times this quantity is used. The reason for this is that the decomposition of carbide and water into acetylene and lime liberates heat. The quantity liberated from good carbide is 730.73 B.T.U. per pound of carbide. One pound of carbide will raise the temperature of 8½ lb. (one gallon) of water about 87°F. Cool generation is essential, as at temperatures in the neighborhood of 700° C. acetylene becomes polymerized, forming benzine and other hydrocarbons, which condense in the pipes and cause great difficulty.

Centre of pressure of any plane surface immersed in a liquid is given by the following rule: Find the moment of inertia of the surface and its statical moment, both with reference to an axis situated at the intersection of the plane of the surface with the water-level. Divide the former by the latter, and the quotient is the perpendicular distance from that axis to the centre of pressure. The statical moment of a surface is its area multiplied by the distance of its centre of gravity from the given axis. The moments of inertia of plane surfaces, with reference to an axis through the centre of gravity, are deduced in Arrows on theoretical mechanics. The following are a few values, the axis being parallel to the base of the rectangle or triangle:

For a rectangle of base \( b \) and depth \( d \), \( I = \frac{1}{12}bd^3 \).

For a triangle of base \( b \) and altitude \( d \), \( I = \frac{1}{48}bd^3 \).

For a circle with diameter \( d \), \( I = \frac{1}{16} \pi d^4 \).

To find from these the moment of inertia with reference to a parallel axis, the formula \( I' = I + Kd^2 \) may be used, in which \( A \) is the area of the surface, \( K \) the distance between the two axes, and \( I' \) the moment of inertia required.

Section-lining or cross-hatching may be accurately spaced by the simple scheme illustrated herewith. \( A \) is an ordinary draftsman’s triangle, and \( B \) is some convenient coin a trifle smaller than the triangular hole in the centre of the triangle. The spacing is obtained by alternately moving the coin while the triangle remains stationary, and moving the triangle

while the coin remains stationary. If no coin of suitable size can be obtained, it is but the work of a minute to cut a circular piece of cardboard, which will serve. A number of pieces may be prepared, thus giving different widths of spacing. With a little practice the process becomes automatic, and may be carried along much faster than when the spacing is done by the eye.
Electric Counter-Balanced Hoist.

The Editor:

Sir—In regard to recent discussions on counter-balancing of hoists, I enclose a photograph of a hoist installed at the Tepeyac mine. This was built by the Denver Engineering Works, and is their single-drum 50-hp. Cripple Creek type, but was equipped with a 33-hp. motor. The mine developed so rapidly that, under pressure of additional tonnage, the 33-hp. motor, (a Westinghouse of the old type) was run for six months at 65 hp., the hoist being in continual service 24 hr. per day, and the motor stood the test.

To relieve the motor and get still greater tonnage, the drum was divided in two by a locally made cast-iron flange (shown in the centre), made in two pieces, bolted together loose on the drum, and secured in place end-wise by pine lagging-strips bolted to the drum on both sides, and filling the space between the end flanges and the central dividing flange. As these lagging strips were 6 in. thick, the diameter of the drum was increased from 36 to 48 in., and by change of gear-ratio from the motor a further increase of rope-speed was made, amounting, together with the increase of the diameter of the drum, to a 50% increase of hoisting speed. A counter-balance of the same type as is used in passenger elevators was then hung in the shaft on wire guides, simply secured at the top and bottom of the shaft, and a 7/8-in. rope led over a pulley in the head-frame to one division of the drum, the hoisting rope occupying the other division. The counter-balance weight was calculated to equal the full weight of the cage, car, and one-half the ore to be hoisted, so that the motor works equally both raising and lowering.

The sum total was that the ore per trip was increased from 1600 to 2200 lb.; the hoisting-speed increased from 400 to 600 ft. per minute; and the motor now uses 23 instead of 65 hp. The hoist has been in use in this shape for nearly a year under the above conditions, and has proved most satisfactory. It is hoisting 24 hr. per day from a depth of 650 feet.

Sampling of Ore.

The Editor:

Sir—In many of the articles on ore sampling which have recently appeared in the different mining journals there appears to be a manifest desire to discredit the usual methods of ore valuation, but most of the writers evade the real question at issue, and evince a distrust of all methods of sampling, instead of directly specifying those that are known to give erroneous results. The action of crushing machines in retarding the speed of the coarser particles is as well known as the increased rate of travel of the coarser particles in spouts and on the sides of ore piles. In a properly designed sampling machine which takes exactly the same proportion of coarse ore that it does of the fine, this difference in the rate of travel could have absolutely no effect on the sample. In fact, if a given lot of ore were screened and the coarser portion sampled today and the fine tomorrow, and the resultant samples mixed, the result would be exactly the same as if the coarse and fine were sampled together, provided the method of sampling employed took exactly the same proportion of coarse ore that it did of fine. The shaking-tray feeders which one writer mentions are used in all modern crushing and sampling mills for the purpose of delivering a continuous evenly distributed stream of ore to rolls and other crushing machinery in order to minimize wear and prolong the life of the wearing surfaces, and they do not in any way affect the accuracy of the sample; indeed, there is a distinct gain in the use of them, as spasmodically fed crushing machines cannot deliver a product as uniform in size and quantity as similar machines supplied with a steady feed.

A correspondent in your issue of October 17, 1908, mentions the fact that in several instances that have come under his notice, the first sampling of the ore gave lower results than the second. This could only occur in plants where, by accident or design, the methods employed, whether hand or mechanical, took into the sample a larger proportion of coarse ore than of fine, and on the re-sample of the crushed ore, where the ratio of coarse to fine was materially diminished, this sorting action would be less; consequently, the second sample would be considerably higher than the first, provided the fine ore, as is usually the case, assayed higher than the coarse. No sampling machine or method that depends on mixing the ore can ever be accurate, as no amount of turning, whether with a shovel or by mechanical means, can effect a perfect mixture of coarse and fine material. During the process of crushing ore, and in its passage through the spouting, piling up on the floor, or even in filling bins, a continuous sizing action is going on.

To sample ore accurately, some ‘time sampling’ device is necessary, or, in other words, some arrangement that will take a sample which shall be entirely independent of the physical condition of the ore, and will give exactly the same percentage of fine and coarse, no matter what the size of the particles may be or the amount of moisture contained therein. A number of machines on the market are capable of
The Editor:

Sir—On reading over my article which appears in your issue of October 31, I notice the following error in transcribing my notes: Commenting on the old tailing-wheel formerly in operation at the new mill of the Smuggler-Union Mining Co., at Telluride, Colorado, I state that it is doubtful if this wheel required over 15 hp. to operate. This should have read 5 horse-power.

Shallow Deposits.

The Editor:

Sir—About half a mile south of the town of Del Norte, in southern Colorado, is a small knoll formed by a tilted flow of rhyolite. It is partly covered by a very recent conformable basalt flow 50 ft. thick, and from the appearance of the rhyolite it would seem to be of the same age as the basalt, probably Pleistocene. On the road to the summit of the hill there is a small vein of chalcedony or jasper 5 to 6 in. wide. It assayed $1.20 in gold and no silver. Would this not seem to show, contrary to most text-books, that mineral deposits can sometimes be formed at very moderate depths?

I should like to know if others have ever observed the same phenomena.

Thrayer Lindsley.

Telluride, Colorado, October 27.

Sampling Ore.

The Editor:

Sir—In one of the recent numbers of your journal, I noticed the following paragraph: “The alternate shovel method of sampling ore is cheaper and quicker than the coning and quartering method, and is apt to give a closer approximation to absolute accuracy unless the coning is very carefully done.” I should be glad to know whether this statement is based upon experiment, and if so, where the records of the experiments are obtainable.

I did some work on this point myself in the year 1905, and the results I obtained were published in one of the Bulletins of the Institution of Mining and Metallurgy. My conclusions were the exact opposite to those given above, as regards the accuracy of the methods, which is after all the important point in sampling. In point of time, if the mixing of the samples between each cut is done by rolling on canvas, there is very little to choose between the methods. It seems to me that the alternate shovel method of sampling is open to two main objections. First, it allows too much chance of selection. It is quite easy for the man who is doing the shoveling to arrange that any specially rich-looking stone should go into the keep portion, rather than the reject, and this would be a natural tendency, quite apart from any outside interference. Secondly, it is not easy to get a fair proportion of the fine in each half. In throwing a sample into a heap, as is done in mixing it, the fine gravitates to the centre of the pile, the result being that in shoveling the sample, the last shovelful...

IRON ORE DEPOSITS IN SHASTA COUNTY, CALIFORNIA.

In view of the successful tests for the production of pig-iron on a commercial scale, recently carried out at Heroult, the extent and value of the magnetite deposits of Shasta county are naturally attracting attention. The experiments have demonstrated that pig-iron can be successfully produced by electric smelting at comparatively low costs, while the objections to the old Heroult plant have been practically eliminated by the improved Lyon furnace. The production of pig-iron in Shasta county on a large scale seems now to be assured, and the interested parties are turning their attention to the development of the magnetite deposits.

The principal deposits of iron in Shasta county lie along the McCloud river, the ore occurring between the Carboniferous limestone and the contiguous rocks. Where the Pit river has cut across the formation in its westerly course the indications are favorable from the higher points of the canyon to the river bed, 1500 ft. below. Practically all the mine development in the district is concentrated at this point. The limestone belt continues from the head of Stillwater creek about six miles south of the Pit river and several miles in a northerly direction.

A few miles above the confluence of the Pit and McCloud rivers, Potter creek cuts across the country from the east and exposes a large lode of magnetite, which at some points runs from 400 to 500 ft. above the level of the stream. The deposits occur between limestone and diorite, and apparently have a north-easterly and southwesterly strike. Sufficient work has not been carried on here to determine the magnitude or extent of the deposits, but the indications are excellent.

Active exploration and development is centred on the Pit mine, lying in Section 26 on the McCloud river, and owned and operated by the Shasta Iron Co. This property has been held for its value as an iron producer since 1884, and for a number of years much of the production was shipped to the Bully Hill smelter at Deflemar for fluxing purposes. The quarry from which this ore was taken is approximately 200 ft. below the apex of the mountain. At a point 100 ft. below the floor of the quarry an adit has been driven for about 150 ft. The lode is apparently 150 ft. thick at the quarry, with a fair percentage of iron. The iron content shown in the adit is estimated to be from 50 to 70%. At the summit of the mountain the croppings appear to be about 250 ft. wide, and have been traced for 1500 ft. on the estate of the Shasta Iron Co. Indications are good for opening up a vast tonnage of commercial ore. It is estimated that the average value of the ore will run about 65% iron, with little sulphur or phosphorus.

The Noble Electric Smelting Co., controlling the Heroult smelter, has entered into an agreement with the Shasta Iron Co. to treat the ore on a large scale as soon as the plant has been placed in commission, and has also secured options on many properties along the McCloud river.

T. LANE CARTER.
From Lake City the trail leads up Henson creek, over the divide just north of Engineer mountain, and down Bear creek to Ouray, a distance of about 20 miles. Here, again, to accomplish the journey by rail requires a whole day, with two changes, passing through Sapinero, Montrose, and Ridgway. The entrance to Ouray is through a narrow gorge, where river, railroad, and trail jostle each other. The walls rise steeply for nearly 1500 ft. on either hand. Farther on the valley widens into a roughly semi-circular form, and to the east is the huge glacial cirque known as the Amphitheatre, with walls rising to over 11,000 ft. From all sides streams pour down through canyons of great beauty. With its hot springs and other attractive surroundings, Ouray will always excite the interest and admiration of the visitor, whatever may be his taste.

The history of Ouray began about 1875. The railroad that gave impetus to its development arrived in 1887. Ouray is one of the best localities to study the geology of the San Juan. From the Algokian quartzites in the canyon of the Uncompahgre to the San Juan tuff that caps the summits of the surrounding mountains, the entire geological column is well exposed. The Paleozoic and Mesozoic sediments dip to the northwest at a gentle angle. The ores occur in all horizons between the quartzite and the tuff, and in some cases even extend into the latter. The replacement deposits are generally in limestone or sandstone (quartzite). One of the best examples of this type of deposit is the Mineral Farm mine, which for many years has been working a replacement near the top of the Ouray (Devonian) limestone, about a mile south of Ouray. Recently Mr. Duprau, the superintendent, by a clever combination of geologic reasoning and ‘gumption,’ has opened up another large body to the south of the old workings. The ore lies partly in the Ouray limestone and partly in a thin bed of cherty conglomerate, the lowest bed of the Hermosa (Lower Carboniferous) formation. Immediately above this is a thin bed of shale that has been faulted and changed into a tight ‘talcose’ band, which has served to confine the rising solutions and to limit the zone of ore deposition. The ore extends downward from this horizon, and is at present opened up 200 ft. east and west and 850 ft. north and south, dipping south with the contact between the Hermosa and the Ouray about 25 ft. per 100 ft. Galena predominates, with associated tetrahedrite, which carries the silver. It is treated by crushing with stamps and then concentrated on bumping tables and vanners; the tailing is run to waste over long and wide canvas tables, where a good saving is made.

The deposits around Ouray possess great interest and have often been described. I shall only mention a few of the more important features. Noteworthy are the curious elastic dikes, first described by Ransome. These occur in several places in the Mesozoic rocks, and consist of fragments of sedimentary rocks of a different nature from the enclosing walls, thus distinguishing them from fault-breccias, which they otherwise resemble. Ransome has suggested that when fissures had opened through the sediments, fragments of the overhanging shale falling into the opening were afterward consolidated by pressure. Rickard believes that the filling came from the forcing upward of underlying shale by pressure. Irvine has suggested that, being made up of sandstone and shale fragments, the dikes had an original composition approaching that of portland cement, and upon the passage of thermal waters through them they ‘set.’ This, much better than the pressure theory, would serve to explain the way in which fine stringers from the dike branch off into the walls.

Of the former producers, only a few of the more important can be mentioned. The American Nettie was an interesting replacement in quartzite that produced large amounts of good ore, but is now nearly exhausted. The Bachelor, in common with two or three smaller companies on the same vein, took out large quantities of ore from a persistent vein. It was in the workings of the Bachelor that the elastic dikes were first observed. The Bright Diamond mine had two sets of workings, in one of which the usual lead-silver ores occurred; in the other a deposit of pyrite, magnetite, and garnet: this had a good gold content, but was too refractory for profitable treatment. Among the present operators are the Calico Tunnel & Mines Co., which has consolidated several properties in Dexter gulch and is working on a larger scale. Another is the Chipeta tunnel, being driven in the hope of cutting extensions of the large orebodies formerly mined. The Ouray Consolidated is similarly driving an adit to intersect several veins.

In the early days Ouray was a smelting centre, until the advent of the railroad made it more profitable to ship the ores. A few years ago another attempt was made to operate a smelter, but it was not a success, and now, with the exception of a small sampling works, nothing remains but some scattered machinery and partly dismantled buildings.

Ouray is the point of departure for the pack-trains that go to many mines situated on the mountain sides. It will readily be appreciated that in an area where the gradients are so excessively steep, mules or burros are the only practical means of transportation. The accompanying illustration (Fig. 7) shows a mule team loaded with planks, about to start for a neighboring property. Mules are usually tied together in a continuous string, while the burro-driver herds his train before him as he might a flock of sheep. It is a marvel of brute ingenuity to observe how a mule carrying 14-ft. planks manages to get around the exceedingly sharp turns or ‘switchbacks’ on the trail. They do it without mishap except at rare intervals. The burro is found throughout the San Juan, patient, willing, and unobtrusive, except at times, when, in the stillness of the night hours, the
wells in his soul impels him to break forth into a song that, whatever it may express to him, is remarkably like the sound produced by actively filing a 4-ft. buzz-saw.

The largest mine tributary to Ouray is the Camp Bird, situated in Imogene basin near the head of Canyon creek. The early history of this mine is an unfolding topic of conversation where mining men foregather. After having made a substantial fortune for Thomas F. Walsh, it was acquired by the Camp Bird, Ltd., and is being vigorously and successfully worked by that company. The mine is at an elevation of 11,500 ft., and is opened by an adit about a mile long; raises extend above this for about 1000 ft., and winzes 300 ft. below. The haulage in the adit is by a Westinghouse electric locomotive, and the hoisting in the winzes and the lowering in the raises is done by electric hoists. All the power is electric, and is transmitted at 10,000 volts from Animas, Silverton, and Telluride, so that the plant would not be closed down by the failure of any one transmission line. This is further prevented by a storage-battery plant of a capacity of 600 ampere-hours, always kept in readiness for an emergency. The men work in 8-hr. shifts. The wage scale is the usual one for the district, except that the machineman and his helper each receive the same wage. About 100 men are employed. They receive good wages, live in the company's boarding-house (shown to the right in Fig. 8), where the food and accommodations are superior to those at the hotels in any but the larger towns. Billiard and pool tables, magazines and books, are provided also, and the total charge for all this is one dollar per day. The cost of living throughout the San Juan averages considerably over that sum. In spite of this it is difficult to obtain men; for several months in the winter it is almost impossible to get out because of the snow, and the average miner seems to object to placing himself in a position where he cannot reach saloons and gambling-houses when the mood seizes him.

The Camp Bird mill is on Canyon creek, about three miles below the mine. It contains 60 stamps, and treats 275 to 300 tons per day. Each stamp weighs 1050 lb., and drops 120 times per minute. Each battery is provided with 24 ft. of silvered plate of the same width as the battery. The overflow from the plates goes to 24 six-foot vanners. The tailing from these goes to classifiers, and the overflow from them to Wilfley tables, the spigot-product being reground in 5 Huntington mills, which crush through 35 and 40-mesh screens, the pulp flowing over 15 ft. of amalgamating plates. Thence the pulp is concentrated on 6 more vanners, the tailing from these, combined with the Wilfley tailing, going to the cyanide plant. Here it is elevated by a sand-pump and classified in a 15-ft. spitzkasten. The slime overflows to waste, the sand being leached by percolation with 0.25% cyanide solution. The concentrate from the mill is sacked and 'packed' to Ouray, whence it is shipped to the smelter. It assays about 9 to 10% lead, 12 to 15% zinc, 11 to 15 oz. silver, and 2½ to 4 oz. gold per ton, and represents about 10% of the weight and 20% of the value of the crude ore. The total recovery of the gold is a little over 95½%. The total cost for mining, milling, and general expense per ton of ore is about $10, the cost of cyaniding the tailing being a little less than 70¢ per ton, which seems high, considering how it is done. The former mill was wrecked by a snowslide on March 17, 1906, and totally destroyed by fire three days later. The work of re-construction was carried on at
a record-breaking pace, and the stamps were again dropping before the end of the year. Advantage was taken of the re-construction to increase the weight of the stamps and the length of the plates.

To Telluride one can go from Camp Bird mill by way of Mount Sueslies, passing the Virginian mine, and some promising prospects, or by way of the mine over the divide, at an elevation of 13,300 ft., to Savage basin and thence into Telluride, four miles away and nearly 5000 ft. below. Telluride, geologically, presents no striking contrast to Ouray. It is situated in a narrow glacial valley, now occupied by the San Miguel river and its tributaries. Along its sides lateral moraines are visible, and a few miles below Telluride, near Keystone, is the terminal moraine. The tributary valleys head in glaciated cirques. How steep the slopes are is shown in Fig. 9, which shows the Smuggler-Union mill at Pandora, two miles above the Telluride, with the Bridal Veil fall in the background. The necessity for pack-trains for transport is easily appreciated from a glance at the zig-zag line of the trail on the far slope. The geological section exposed is higher than at Ouray, the lowest beds being Lower Carboniferous. The dip is slightly to the west, and the overlying volcanics form a thick series. Between Ouray and Telluride, on the heights to the west of Canyon creek, is an extensive flow of quartz-monzonite porphyry. In contrast to Ouray, most of the valuable deposits are in the Tertiary volcanics, rather than in the Paleozoic and Mesozoic sediments. The fissure-vein and the fillings of sheet-zones are the more important, although a certain degree of wider replacement is not lacking. The ore deposits of Telluride have been described in length by Whitman Cross and C. W. Purington.1

The veins of Telluride were discovered in 1875. By 1890 the railroad was completed to the camp. The three principal producers at Telluride are the Tomboy, the Smuggler-Union, and the Liberty Bell. The Japan-Flora and the newly developed Black Bear, said to be on an extension of the Tomboy vein, are also worth mention. The Black Bear was discovered and developed by Finnish miners. The Smuggler-Union has two mills in the valley, connected by long aerial tramways with the mine openings in the high basins to the north. The small mill has a capacity of 300 tons per day, and the larger one 350. The two mills are only about 200 yards apart. The Tomboy is managed in a most business-like manner, and an effort is made to extract the ore so as to mill a mixture representing the average grade of the reserves. Thus an average net profit of $40,000 per month is steadily maintained and opportunities to indulge in stock speculation are minimized.

The Liberty Bell mine and mill are among the most interesting in the district. The mine is in Cornet basin, and is connected by a two-mile aerial tramway with the mill on the banks of the San Miguel, just above Telluride. As the grade is heavy the speed is controlled by a double band-brake, and also by an absorption pump that pumps oil through a needle valve-like opening, the size of the opening determining the amount absorbed, its maximum capacity being 50 hp. The Liberty Bell vein has a strike of 50 to 60° southeast and dips 33° southwest. The average thickness of the vein is 3½ ft., though it is at times as wide as 10 ft. The hanging wall has been subjected to a small movement laterally to the southeast. The vein-filling consists of included wall-rock, frequently decomposed to a rather mushy mass, with longitudinal bands of quartz intermixed with calcite, which often shows well developed crystals. Pyrite is present in large amount, but galena, spharite, and probably sulphides of silver are important constituents. A perceptible amount of arsenic is present in the average mill-ore, which must exist in the form of oxy-salts, as in re-casting the chemical analysis there does not seem to be an equivalent of metallic bases to combine with it after the sulphur is satisfied. The quartz is often blackened by included oxides of manganese, and the vein is vuggy in many places. The large amount of clay in the ore makes it hard to handle in the tram-buckets and on the belt-conveyor over the mill bins. Neither does it run well on the foot-wall of the stopes, so a skip has been installed to let down the ore from the upper levels to the working level. The present workings are entered by a short adit to the vein, and a drift 4000 ft. on the vein. There are three other levels, 250 ft. apart, above the working level. The vein has also been cut 1000 ft. lower, by an adit 2800 ft. long. The lower adit is almost on the contact between the Telluride conglomerate and the San Juan tuff. Whether the vein will be profitable through the sedimentaries remains to be proved.

Fig. 11 shows the Liberty Bell mill. In the mill the ore from the tramway is distributed into the bins above the stamps by a belt-conveyor. There are 80 stamps of 850 lb. each, making 100 drops per minute, crushing through a 20-mesh screen. The capacity is 300 tons per day. When the silver in the ore is low, the ordinary screens are replaced by 14-mesh, increasing the capacity to 375 tons per day, and giving an equally good gold extraction. The plates below the batteries are 4 ft. 11 in. by 8 ft. Some of the plates have four drops in their length, some have three, and others two, but the increased efficiency of amalgamation often claimed to result from using a large number of drops is not conspicuously shown in the experience at this mill. The plates are kept soft. It is thought that this is made necessary by reason of crushing in cyanide solution, 1½ lb. KCy per ton being used. Why cyanide solution should harden plates is not obvious. It seems more probable that, since the cyanide solution always keeps the plates bright, it is possible to keep them softer without flowing than when the plates are partly diseolved, and, of course, the thicker the mercureic film on the plates, the more favorable are the conditions for amalgamation. The overflow from the plates goes to Dorr classifiers, the slime from these to the cyanide plant, and the sand to 22-ft. tube-mills. The ground product from the tube-mills is again classified, and the sands returned to the tube-mills, so that the entire product is reduced to slime before being sent to the

1 Bulletin No. 132. U. S. G. S.
cyanide plant. All the slimes on their way to the cyanide plant pass over an additional 8 ft. of amalgamating plate. The slime-tank, when full, is allowed to settle for 12 hr.; the clear supernatant solution is siphoned and run through a set of Moore filter-leaves before going to the zinc-boxes. The thickened pulp is run into a vat, where it is agitated for 12 hr. by a screw-propeller pump. It then goes to a 21 by 10-ft. filter-vat, where it is kept in circulation by three air-lift streams. The filtering is done by the Moore system. A noteworthy feature is the measuring vat for the cyanide solution, before it is sent to the zinc-boxes. This is a tilting vat. The jar is minimized by the use of a large umbrella-shaped submerged frame, which acts like a dashpot. The amount of solution is registered by an automatic counter. The cyanide tailing goes to the concentrating plant. Here it is classified into fine sand and slime. The fine sand is treated on Willey tables, and the slime goes over a large extent of canvas tables. What is caught on these is re-treated on vanners. The amount saved by this concentration is not high, except when the silver happens to be abundant. Two-thirds of the gold is caught on the battery plates.

The Liberty Bell illustrates what technical training, combined with native ability, is able to do for a young man. Edward H. Nutter, himself a young Leland Stanford man, informed me that on his force 11 technical schools, colleges, and universities were represented in all sorts of capacities, such as sampling, assaying, surveying, as shift-bosses, and even as ordinary miners. The mill superintendent, W. E. Tracy, a graduate from the Columbia School of Mines, is probably the youngest as well as one of the ablest mill-men in Colorado. This is significant.

From Telluride there are several trails to Silverton. One zigzags up the slope, leads through the Bridal Veil basin, over the divide. Another way is through Savage basin, turning to the east at the top of the divide and coming down into Red Mountain, whence there is a daily train to Silverton. The trail is not one to be lightly adventured at any time except in summer, as may be inferred from Fig. 12, photographed just beyond the crest. Skirting the western slopes of Red Mountain are Ironton and Red Mountain, once scenes of activity, but now, barring a few exceptions, very dull. Descending the slope, we come near Red Mountain, to the workings of the Gus-ton, Genesee-Vanderbilt, Yankee Girl, Elbert, and other properties that have consolidated into one corporation. A long drainage adit has been driven to unwater them. From the summit, a little beyond Red Mountain, down into Silverton is a 5.8% grade. The railroad is the first one built by Otto Mears after having done such splendid pioneer service in building wagon-roads. The San Juan owes more to his sturdy optimism and energy than is often realized.

On the outskirts of Silverton is a partly dismantled smelter that is eloquent of the fate that awaits any attempt to treat such ores remote from fuel and supplies, and where barren flux must be bought. I hold no brief for the smelter trust, nor do I deny that their charges are often excessive, but it seems...
reasonably clear that a small plant, attempting to operate under conditions that are irregular and often adverse, is not a sound business venture. Silverton's list of former smelters is rather long, and some of the interesting features of the early days have been recited by T. A. Rickard. It still possesses one plant that has lately been in operation, but the Durango smelter of the American Smelting & Refining Co. treats the larger part of the ores from this district.

Adjacent to Silverton are many large producers. Up Cement creek the Gold King Mines Co. operates a railroad to Gladstone, where the Gold King has an 80-stamp mill of modern design, with tube-mills for sliming. A stone's throw away is the Mogul, which operates a 30-stamp mill, with a complicated arrangement of jigs, tables, roasters, and with Blake-Morcher and Wetherill electric separators at the end. Up at the head of the little gulch to the east is as beautifully developed glacial cirque as a geologist could wish to see, but even his geologic fervor is not likely to make him oblivious to the delicious wild strawberries in the valley below it. Near Silverton are numerous productive mines. The Detroit & Colorado, Champion, Silver Wing, Sunnyside, Aspen, Iow-A-Tiger, and Old Hundred, all add materially to the monthly tonnage. A railroad built by Otto Mears pushes its way up the canyon of the Animas, past Eureka to Animas Forks.

The most active property here is the Gold Prince, operating a new 100-stamp mill that is worth more than a casual observation. There are 10 batteries of 10 stamps each, and each battery is driven by its own 20-hp. 3-phase, 440-volt Bullock induction-motor. Thus it remains unaffected by a mishap to one of its neighbors. The plates are the width of the battery and 8 ft. long. Gear ed sand-pumps elevate the tailing to spitzlutten, which make first and second spigot-products and an overflow. The first spigot feeds 20 Willey tables. The tailing is re-ground in tube-mills. The concentrate is shoveled directly into buckets of 1000-lb. capacity running on an overhead carrier. The tables are driven by induction motors kept dry by suspending them from overhead framing. The rest of the mill was not in operation at the time of my visit, but the finer products are to be treated on 50 Card tables. The concentrate is dried on a steam-jacketed pan before being sacked for shipment, in order to save freight.

Before leaving Animas Forks the traveler should climb to the top of Wood mountain to see the majestic circle of the snow-clad peaks of the San Juan. Looking north one dimly discerns the level line of the Grand River mesa, 140 miles away, while closer at hand tower the great peaks of Uncompahgre and his brothers. Just below is the rolling expanse of Poughkeepsie park. In the west peak after peak fades into the dim line of the distant La Platas. Southward the silver ribbon of the Animas winds down the valley 2500 ft. below, until it turns out of sight above Eureka. Here and there are inconspicuous lines of telephone and electric transmission, the latter without doubt the most significant feature in the present development of the San Juan. From Animas, Telluride, and Ouray they come threading the gulches and displacing the patient burro. One cannot escape the impression that the San Juan is no longer a "poor man's country." Gold placers were never here. The rich silver bonanzas have been largely extracted in the thirty years past. Large bodies of moderately low-grade ore, often difficult to mill, are still abundant; but only ample capital and thorough knowledge and experience can exploit them profitably. The day when pluck, endurance, and a little good luck could often make a fortune in the San Juan has gone by. Mining now demands money, good judgment, experience, and the utilization of every resource of technical knowledge.

No account of the San Juan would be complete without following the ore and concentrate shipments to their destination. The smelting plant at Durango treats a goodly quantity from the southwestern San Juan, but greater quantities find their way to Pueblo, Leadville and Salida. The base bullion produced is sent to Oua ha for further treatment. The plant that is best adapted to the peculiar difficulties of the San Juan ores is that of the United States Smelting & Refining Co., at Canyon City (Fig. 13). Here is in operation the Lewis and Bartlett bag-house process, devised to solve the problem of smelting lead ores high in zinc and containing important amounts of the precious metals. It consists in volatilizing the lead and zinc as oxides, while the copper, gold, and silver remain in the residue, to be smelted for matte. The present operation differs little from the familiar description in Hofman's 'Metallurgy of Lead,' except that the side-feed of the roasting-hearth is no longer used, hand-feeding from the front being found more satisfactory. The 36 by 108-in. shaft-furnaces use an extraordinary amount of air, the aim being to eliminate the lead and zinc and to secure a white 'smoke' or fume. The fume is caught in unwashed woolen bags, and is refined in small roasting-furnaces to the grade commercially required as a pigment. The matte from the shaft-furnaces goes to matte-smelting plants. A similar larger plant is to be built about one and a half miles south by another company.

Between these sites is the plant of the Empire Zinc Co., which concentrates zinc ores in the wet way and also by Wetherill magnetic separators. The Leadville ores are not difficult to treat, as the zinc-blende they contain is the non-bearing variety known as marmatite, which is already magnetic enough to lend itself to direct magnetic separation. The San Juan zinc-blende, however, is the non-magnetic variety, and to separate it magnetically from pyrite it is necessary to roast enough to make the latter magnetic. This requires coal, and the resulting fume soon causes a disturbance among the owners of surrounding vegetation. So the owner of a mine the ores from which are too high in zinc to escape the smelter's penalty, too high in pyrite to make a good zinc concentrate, or high in precious metal (for which the zinc smelter does not pay), possesses a keen interest in every advance in ore-dressing and metallurgy.

OREGON QUICKSILVER.

The last edition of 'The Mineral Industry' contains the following article by William B. Dennis, manager of the Black Butte quicksilver mine, of Lane county, Oregon: The reduction plant at the Black Butte mine, Lane county, was not operated during 1907. The year was consumed in installing a new plant. Some underground work was done, chiefly preparations for stoping. The mine itself had been extensively developed during previous years and large ore-reserves established. The property includes about 2000 acres of timber land and lies in the foot-hills of the California range, at the southern extremity of the coast fork of the Willamette valley. Several clearly defined lodes of cinnaabar-bearing rock have been proved. The ore occurs chiefly along fracture planes, which show marked persistency in lineal and vertical extension. Along these fractures the ore-bearing solutions have penetrated the walls laterally for a great distance, forming wide ore-bodies. One main central fracture, outcropping along the apex, virtually cuts the mountain in two longitudinally. This fracture has been traced in a continuous line for two miles, showing ore-bearing rocks at every exposure. The richer portions of the lode usually lie along the walls of the fractures, forming payable ore-bodies ranging from 8 to 80 ft. wide, and containing an average of from 0.25 to 0.57% mercury.

The rocks of the region are of volcanic origin, tufts being abundant. The extent of alteration is so great that it is difficult to determine the original composition, but geologists who have examined the district have generally agreed that they are originally andesites. The problem in the operation of the Black Butte mine has been to treat the large low-grade ore-bodies at a profit. Former owners had erected a 40-ton Scott-Butler furnace of the California type. The operation of this plant proved unprofitable, as it saved only 33% of the metal. The fire-wood of the district, used for fuel, produced an enormous amount of soot, which retarded condensation, and made a second treatment necessary in order to free the quicksilver from the soot. In 1906 there was erected an experimental furnace on new and original lines, and the design was patented. Perfect combustion was accomplished, soot entirely dispensed with, and a high percentage of recovery secured. The roasting period was cut down from 24 to 6 hr., thereby greatly increasing the furnace capacity per unit of hearth area. Along the lines of the new process a plant, including alterations to portions of the old plant, was erected during 1907, and on February 1, 1908, the fires were lighted. The ultimate success of the new plant still remains to be demonstrated, but in the early part of March the outlook was favorable.

The new plant is equipped with a hydro-electric power which supplies current for lighting the buildings and mine, and power for the operation of the crushers and the two 70-ton Sturtevant exhaust fans. These fans furnish artificial draft for the furnace, as well as for the wood-gas producer, which is also one of the new features of the plant. A Sturtevant coarse ore breaker and a fine ore Gates crusher have been installed, and bin capacity for 700 tons has been provided. The ore is delivered to the furnace by an aerial tramway 3000 ft. long. The condensing plant has been erected along new lines and forms one of the novel features of the plant. The new dryer, constructed of concrete, steel, and brick, has a net capacity of 125 tons.

CHILEAN PULVERIZER.

Written for the Mining and Scientific Press
By Douglas Waterman.

The accompanying cut is typical of the pulverizer to be found in the assay-office of every Chilean mine. It consists of a circular cast iron plate with rim and spout, with an iron muller weighing over 200 lb. The stem is about 3 ft. long, and the muller may be operated conveniently from a standing position.

The sample as it comes from the mine is first spread on the plate, and the large pieces broken with a hammer. If the sample is of large bulk, it is coned and quartered in the usual manner, the spout facilitating the thorough cleaning of the plate. The muller is then brought into use. It has a slightly convex face, and both a rocking and revolving motion is imparted to it with the expenditure of comparatively little labor on the part of the operator. By the combination of motions the muller may be made to travel over the surface of the plate, the crushed ore being loosened and the coarser particles brought to the surface by gently tapping with a broom. The sample is quartered on the plate as grinding proceeds, and the final assay-sample reduced from 30 to 100-mesh in a Wedgewood mortar.

The method is a fairly rapid one, but has no points of superiority over the mechanical crusher and mortar.

Gypsum occurs in several forms which differ in form, texture, and color. The most common form in which it is found in workable deposits is as massive or rock gypsum. Alabaster, occasionally used for statuary, and gypsum earth or graphite are other commercial varieties. The pure mineral is white and, when in crystalline form, translucent. The impurities which it commonly contains usually destroy the transluency and affect its color, so that the mineral as mined is an opaque finely grained mass, varying from white to reddish gray or brown in color.
RAND SAMPLING PRACTICE.

Written for the Mining and Scientific Press
By J. S. Oliver.

The problem of taking an equal weight over the width of a reef is not as simple as it would appear. The face to be sampled seldom presents a flat surface, and when it does so it is often so hard that it becomes a physical impossibility to take a sample from it. On an irregular surface the prominent parts are naturally the most easily chipped off, and it is often impossible in such a case to cut an even sample straight across. I think it good practice in this instance not to confine oneself to a given line, either perpendicular or diagonal to the plane of the vein, but to depart slightly on either side of the true line. In taking a sample in this way it is essential that the portion taken on one side of the line be in the same horizon as if it had been taken on the line.

A heavy sampling pick should always be carried, in addition to the hammer and chisel. Not only is the former indispensable when examining a stope or drift, but a sample can be taken both more quickly and more accurately with it in soft or shattered ground. When the pick is used the sample should not be caught directly in a dish, but in the hand, because it is impossible when the ground is shattered to insure that only the required portions of rock fall into the dish. Every piece of rock which goes into the sample should be followed with the eye, and its comparative size estimated. No chips which have missed the dish should be picked up from the ground. When a large piece has been broken off, and it is necessary to reject a part, the sampler must be sure, before he proceeds to break the stone, that he knows exactly how it lay in place; otherwise an excess may be taken from one horizon and nothing from another.

The mistakes to be feared are those which are the result of a constant personal bias in one direction. The law of averages is always on the side of the intelligent and careful sampler, since it tends in time to eliminate accidental errors, but it does not help the man who works on wrong principles. The personal bias of an untrained sampler is almost invariably in the direction of excess in value. One of these dangerous tendencies has been indicated in the liability to take more than the fair share of the richer portion of the vein. The most common and the most difficult to avoid is in correctly measuring the width of the sample. This error tends in the great majority of cases to produce too high a value. A measurement along the face will always be too great, except where the face lies in a plane perpendicular to the plane of the vein, and the measuring rule is held perpendicularly to the plane. All measurements should be taken with a 2-ft. rule, which is preferable to the tape, but when more than one sample is taken in a section a check measurement, with the tape, if necessary, should always be taken across the whole width and compared with the sum of the widths of the samples and of the intervening waste rock. An excessive estimate of width is likely to be caused when a channel is being cut through tough rock. It often has a tendency to thin out to a knife-edge at the top and bottom. If the measurement is made to the extreme ends of the channel, too high a value will be obtained. Only a portion of the shallow end of the channel should be taken into the width. If this error is not avoided, a further bias toward excessive value will be established.

It must be noted than when some waste rock on either side of the reef is taken into the sample, as it always should be in the case of a distinct leader, the width of waste must be included in the sample width. I have seen a block of ground condemned as unpayable through ignorance of this seemingly self-evident principle.

An error peculiar to stope sampling which must be carefully avoided is the common one of under-estimating the stopping width. The reason for this error is that the narrowest part of a stope is nearly always at the face, and therefore the width where the sample is taken does not represent the average width of the stope. The sampler must always measure the full width at the face in order to check the widths of his samples, but he must not accept that as the stopping width. The latter width must always be taken at some distance from the face, where the permanent width of the stope can be determined. When the hanging wall is not good, especially where machines are being used, the sampler must use his judgment as to what the ultimate width of the stope is likely to be, and he should make a liberal allowance for shattered rock falling away from the hanging wall at some distance from the face. This stuff is sure to become mixed with the ore, and as it is either waste rock or ore of very low grade, it must reduce the value of the stope. The tendency to under-estimate stope width is another instance of bias toward excessive value.

The most elaborate and rigid systems with which I am familiar on the Rand are one which insists on continuous samples of each reef being taken throughout the mine. In the case of a narrow leader, the whole surface of the vein is chipped, from the beginning to the end of the section, each section being 10 ft. long, while in the case of the wider veins continuous zigzags are cut out from top to bottom of the vein and from end to end of the section. This system is certainly thorough, and theoretically there is nothing wrong with it except perhaps that a series of parallel and equi-distant channels across the vein would be preferable to the zigzags, seeing that by the former method each imaginary lamina of the vein would be sampled at regular intervals. But, assuming that this is the most accurate system, is it worth the extra time and trouble? I am convinced by results obtained in several mines that the actual sampling can be done with a maximum probable error of 5%. I refer to the simple system of taking samples of each band of reef at intervals of 10 ft. in the case of reefs of average uniformity, and of 5 ft. in the case of a very patchy vein. Every estimate of milling grade calculated from development must be made upon an assumed stope width and an anticipated percentage of sorting, and the

*Abstract of a paper read before the Institute of Mines Surveyors, Transvaal.
probable error of these together certainly would not be less than 5%. I therefore hold that it is a waste of time to try to reach a maximum probable error of less than 5%. I will go further, and dispute the pre-eminance of the continuous system in point of accuracy. It is a physical impossibility in the average Rand formation to cut out the even grooves which are demanded in this method. The vein is so hard in places that a chisel will scarcely scratch it. In other places the rock breaks off in large lumps or flakes, and where these variations occur within the length of a section, as they constantly do, it is difficult to keep an even weight throughout the sample; while, if the whole length of the section exhibits a shattered surface, the sample becomes unwieldy.

This system does nothing to overcome the personal errors, with the single exception that it does not allow the sampler to select the best-looking spots in a patchy vein; but the best safeguard against errors of that kind is to employ reliable men, and to teach them the principles of sampling. I consider any system of sampling hopelessly wrong which aims at converting the sampler into a machine. The human factor cannot be eliminated from sampling and, if it were, the greatest value of the work would be lost. A sampler, if he is not lacking in keenness and in powers of observation, should obtain an unequaled knowledge of his mine, and it is difficult to overestimate the economic value of this knowledge. A system which is too rigid and too laborious is not well fitted to develop observation and judgment.

Another system in use on the Rand which I consider to be open to objection is that of taking a section across the whole face, including all the bands, into a single sample. The cost of assaying may be reduced in this way, but I feel sure that this is not true economy. More than half the value of sampling lies, not in deciding whether a stope or drift is payable or not, but in supplying information as to the payability of the various layers of the vein.

In another variation of the system a composite sample is made up from all the samples taken from a single leader from top to bottom of a stope. In this method each leader is kept apart from the others, and it therefore meets the demand that every band of the vein should be separately considered; but it has objectionable features of its own. When samples are sent in for assay separately the return of an abnormal assay from any part of the vein immediately attracts attention; a panning is made, and the work is checked, either in the assay office or underground; but a marked contrast in value between one sample and others taken from the same vein is not readily detected when all the samples are put together for assay. Yet one rich sample, inadvertently mixed with several others of low grade, might well make all the difference between payability and unpayability in the average ore, even though that average might not appear to be abnormal. The disturbing value need not necessarily be due to careless work. It often happens in the ease of a patchy vein that one sample comes out abnormally high, while the others show little gold.

The average stoping value may appear to be satisfactory, but a careful sampler will hesitate to accept such a result, and will either repeat the work or cut down the value of the abnormal sample. Again, one of the main objects of sampling is to insure that the proper leaders are being carried, and one of the earliest indications of a mistake in stoping or development is a sudden loss of value. When composite samples are made up, a change in value is scarcely noticeable unless it takes place over a great part of the stope. My final objection to composite samples is that when this method is used it is almost impossible for anyone, on examining the sampling records, to detect mistakes due either to slovenly work or to wrong identification of veins. The undoubtedly saving in cost of assaying does not, in my opinion, justify the adoption of these methods, and it is easy to exaggerate the economy effected, because it must be remembered that a reduction of, say, 20% in the number of assays is not under ordinary conditions accompanied by a proportionate reduction in the cost of running the assay office. It seems to be quite unnecessary to displace the simple method of taking a single section at regular intervals across each band of vein. It is not only the simplest system, but the most rapid; and in the long run it is as accurate as necessary for any practical purpose. A distance of 10 ft. between sections will not be found too great for veins of average uniformity, but patchy bodies should be sampled more closely.

If an even weight per inch is taken in each portion of the composite sample, it is not necessary to keep those portions apart underground, and the whole may be put into one sack. Each portion is measured separately and the average width taken as that of the sample. When this is done, care must be taken that the wider and narrower parts of the leader are represented in the sample according to their lengths along the strike or dip of the vein. This method prevents the unnecessary multiplication of samples, and it gives excellent results; but it should not be used where there is any doubt about the continuity of a leader. The adaptability of this system makes it especially suitable to the sampling of working stopes. The rate of advance of stope faces is variable, and the system should be altered to suit these conditions. When a face is advancing 30 ft. or more per month, the average value of the rock broken during the month will be ascertained with greater certainty by sampling the face twice at intervals of 15 or 20 ft., than by a single sampling, however thorough it may be. Before the stoping values for the month are finally worked out, the surveyor's stope-sheets are examined, and only those samples are included in the average which fall within the area worked during the month. Samples taken in other parts of the stope are carried forward, and only those parts which have been worked in one month are sampled in the next. In this way a record of the whole stope-face is kept up, and a valuation of any part of it can be readily made, while the duplication of samples is avoided. A record of this kind makes it comparatively easy to trace the various leaders throughout a stope.
WASTE FROM BEE-HIVE COOKING.

The coal consumed in retort ovens in 1907, according to the U. S. Geological Survey, amounted to 7,460,587 short tons; the quantity of coal used in bee-hive ovens was 54,485,522 tons, from all of which the possible by-products were apparently wasted. On the assumption that the coal consumed in bee-hive ovens was of the same average quality as that charged into the retort ovens, and that the prices would be not less than 80% of those ruling in 1907, the value of recoverable products which were thus apparently wasted during the year amounted to $41,000,000, a sum equal to nearly 80% of the total value of all the coal used in bee-hive ovens during the year. At the prices which prevailed in 1907 the value of the by-products wasted in bee-hive ovens during the year was a little over $55,000,000.

It should be remembered, however, that bee-hive ovens are situated in the coal-mining regions, and that the cost of the coal charged into them represents only a little more than the expense of mining; whereas in locating by-product recovery plants provision must be made for marketing or utilizing the by-products. For this reason most of the recovery plants are established near the larger cities, and at a considerable distance from the mining regions, and the expense of transportation is thus added to the mining cost of the coal. The cost of the coal charged into the by-product ovens in 1907—7,460,587 tons—was $15,874,430, or over $2 per ton, but the cost of the coal used in the bee-hive ovens was only $1.05 per ton. The original cost of installation for a by-product plant is four to five times that of a bee-hive plant of equal capacity. These disadvantages are in turn partly offset by the higher percentage yield of coke in the retort ovens and the lower delivery-charge on the coke produced. In bee-hive oven practice the expense of railroad transportation is borne by the coke; in retort-oven practice nearly all of the freight charge is borne by the coal.

The total value of the by-product coke produced in the United States in 1907 was $21,665,157, an average of $3.86 per ton. The value of the 35,171,665 tons of bee-hive coke made in the same year was $89,873,969, or $2.56 per ton. If the difference in value of the by-product coke and bee-hive coke was due only to the difference in freight charges, then the total value of the entire product of bee-hive coke made in 1907 would, if made in retort ovens close to the market, have been $135,750,000. If to this be added the value of the by-products that should have been recovered—$44,000,000 at 80% of the market value in 1907—the total value of coke and by-products would have amounted to nearly $180,000,000 instead of $89,873,969 for the bee-hive coke alone, being a gain of about $90,000,000. On the other hand, the cost of the coal charged into the ovens would have been $108,879,570, instead of $56,956,000, this being added expense of about $52,000,000, making the net gain about $38,000,000. This sum, less the difference in the operating expenses, wear and tear, interest on capital, and so forth, may be considered as approximately the actual net loss in 1907 as the result of the production of coke in bee-hive ovens rather than by-product ovens. One of the reasons that has been given for the apparently slow progress in retort-oven building in the last four years is the lack of profitable markets for the by-products of coal tar, and this condition has contributed to the backwardness of the United States in the development of chemical industries depending on coal-tar as a raw material; yet this country is importing coal-tar products to the value of several million dollars annually. It is also well known that the development of the coal-briquetting industry has been retarded because of the lack of assurance of a satisfactory supply of suitable coal-tar pitch for binding material; moreover, there is an increasing demand for cresolating oils for the preservation of lumber. There does not appear to be any trouble in disposing of the ammonia, for which a good demand exists, and the practicability of long-distance transmission of gas has been demonstrated. E. W. Parker says: "When the economies which may be effected by the use of retort ovens have been so clearly demonstrated, not only by the plants which have been constructed in the United States, but more emphatically through the extensive development of by-product coke manufacture in Europe, the condition in the United States, as shown by the statistics of the last four years, is difficult to understand."

Railroad Building.—The Alaska Central runs from Seward, a deep-water port on Resurrection bay, which is about in the centre of the south coast of Alaska, north toward Fairbanks, on the Tanana river. The road is standard gauge, laid with 65-lb. rails. The maximum grade is 1%, except over two mountain ranges, where it is 2.2%. The maximum curvature is 14°. The cuts and fills are heavy and there are seven tunnels and many trestle bridges.

The cost of 54 miles of road was $3,230,000. This includes cost of organization, but not cost of rolling stock, station buildings, docks, office fixtures, etc. The cost of separate sections, starting from the terminus at Seward, was as follows:

<table>
<thead>
<tr>
<th>Section</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 miles</td>
<td>$29,000</td>
</tr>
<tr>
<td>9</td>
<td>$40,000</td>

</tbody>
</table>

The cost per mile of the above 54 miles was $60,000. Deducting the 2½ miles of tunnels and approaches, the cost per mile of 52 miles was $51,000. The two-thirds of a mile of tunnels cost at the rate of $450,000 per mile, and 1½ mile of approaches, $177,000 per mile.—Railroad Age-Gazette.

The deepest bore-hole is at Paruschowitz in Upper Silesia. This is 6573 ft. deep, commencing with a diameter of 12.6 in. and ending with 2.7 in. Mannesmann weldless steel tubes were used for boring-rods.
Empire Hand Prospecting Drill.

The need for an inexpensive and reliable prospecting apparatus for placer work has been keenly felt, and there is no reasonable doubt that considerable placer ground of lying untouched today because of the cost of sampling with power machines. The Empire Hand Drill, manufactured by the New York Engineering Co., offers a solution of the difficulty. It is low in first cost, and the cost of sinking test holes with it is cheaper than by any other known means, and the results are accurate. The amount of labor involved in operating the drill is small, five men and a horse being all that is required, and while the operating expenses are low, from 20 to 50 ft. of 4 to 6 in. hole can be drilled per day, according to the nature of the ground.

An important feature of this drill is the method of driving the casing. This is done by mounting four men on a circular platform screwed on the top of the casing. These men operate the drilling tools inside the casing, while the platform and the casing are rotated by a horse walking around in a circle, and connected to the platform by a sweep attachment, as illustrated: or three of four men may rotate the casing by long wooden handles attached to the platform.

Four men standing on top of the platform give a combined weight of from 500 to 600 lb. The platform will weigh nearly 300 lb. To this is added the weight of the driving tools and the drill rod every time it is lifted by the men; so there is a total weight of over 1000 lb, generally applied in sinking the casing. The rotation of the casing is most important, as it keeps it loose, and it is due to this fact, together with the weight of the men, that the casing usually requires no driving, but sinks into the ground as fast as the core is drilled and removed. Driving the casing destroys both the casing and the joints, and also forces the casing into the ground so hard that it requires enormous effort to pull it. The casing, which is equipped with a sharp toothed cutting-shoe, aids in preparing the core for drilling, and a sand-pump picks up the gravel. Three operations take place at once—that is, the casing is driven or sunk, the core is drilled, and is also pumped, all at the same time; whereas, with all other drills these three operations are done separately and require a large and heavy tools between each operation. The material is removed as soon as it is detached from the core by drilling. This operation proceeds close to the bottom of the casing, or as soon as the core enters the casing, but can never take place below the bottom, owing to the relation between the section-lengths of the rods operating the tools inside of the casing, and the section-lengths of the casing itself. Thus one cannot drill below the casing except when a boulder or buried timber is found. A special drilling bit of extra length is then used for drilling through the obstacle.

Drilling is done by the four men on the platform raising and dropping the rods with the cutting tool attached to the lower end as if they were working a churn drill. A special handle is provided for gripping these square drill rods at any point. The men are not obliged to twist the drilling tools, for the continuous rotation of the casing and platform on which they stand rotates the men and the tools also.

The core is drilled with the regular drill pump. When the pump is filled, it is raised to the surface by disconnecting the rods, and the contents are examined. On completing the hole to bedrock, a bottom sample may be obtained if it is fairly soft, by using the drill-pump with the auger-end attachment. This will bore its way into a soft bedrock and bring up a solid core. The casing is readily pulled by attaching a special pulling cap to the top of the casing, and then a long pole as a lever, with an adjustable fulcrum or pulling stand. Five or six men will be sufficient to pull the casing. The weight of the drilling apparatus is about 1000 lb., and no single piece weighs over 75 lb., except the platform, which can be readily separated into four pieces, each weighing about 75 pounds.

In some recent drilling in Trinity county, California, the records show the following percentages of time devoted to the different operations: 78% in actual drilling; 7% in pulling casing, while 15% of the time was devoted to moving the drill from hole to hole. The small amount of time devoted to pulling the casing shows the ease and facility with which this is accomplished, and it will be noted that most of the time was devoted to actual drilling; also that no time was lost for repairs. The drill is made entirely of steel, no cast iron being used, and it is of such form and construction that it is rendered almost unbreakable. The apparatus has an exceedingly high drilling efficiency, averaging in some ground, as high as 50 ft. of hole per day, at a cost of 25c. per foot.
Decisions Relating to Mining.

MINING CLAIM—AMENDING DECLARATORY STATEMENT.

The filing of an amended declaratory statement of mining claims, under the statute of Montana, cannot create a right of possession or location in the premises claimed under the first statement. The mere fact that this did not exist prior to the filing of such additional certificate. It can confer no additional right, and is therefore evidence of none against any intervening or pre-existing right of another. Hence, except as against such intervening rights, an additional certificate serves the same purpose, in its admission as evidence, as that of an original location-certificate, and will relate back to the location, which was made after the statute is that the additional certificate, or amendatory declarations, show opportunity to cure defects in the original, and thereby to put the locators, where no other rights have intervened, in the same position that he would have occupied if no such defects had occurred.

PLACER CLAIM—LOCATION OF DISCOVERY SHAFT.

The fact that one-half of the diameter of the discovery shaft, measured from the placer mining claim, was held to be a sufficient showing of discovery within such claim; and such claim would not be invalidated by the fact that such discovery shaft was partly on another claim. Neither would it be inferred that the well deviated away from such claim in its descent, in absence of evidence to the contrary.

CONFLICT OF MINING CLAIMS—ADVERSE SUITS—PROOF.

In a contest to determine the title to conflicting mining claims, in order to make out a prima facie case, the plaintiff must show, in addition to the other legal requirements, that the conflicting claim was not covered by a prior location, or, if so, that it was invalid; or that such prior claim had been forfeited for non-performance of annual labor, or that the claim had been abandoned.

Lozar v. Neill, (Mont.) 96 Pac. 343, June, ’08.

CONSENT OF MINING CLAIM—PAROL EVIDENCE OF CONSIDERATION.

Where tenants in common conveyed a definite portion of a mining claim, and the deed was silent as to the terms, parol evidence was admissible to show that the conveyance was made under an agreement, as a part of the consideration, that work done and discovery made by the grantee should inure to the benefit of the grantees.

Morgan Oil Mining Co. v. Patterson, (Cal.) 96 Pac. 99, May, ’08.

FORFEITURE OF MINING CLAIM—RE-LOCATION.

A person attempting to relocate a mining claim on the ground of forfeiture of the original location for failure to make the required improvement, has the burden of establishing such forfeiture. This may be done prima facie, by proof that no labor was performed within the limits of the original claim during the required year. In a case where such prima facie case was made it was held that the burden then shifted to the original locator to show that work performed on an adjacent claim inured to the benefit of the controverted claim.

Fredricks v. Klauser, (Ore.) 96 Pac. 679, July ’08.

MEANING OF 'IMPROVEMENTS' ON A MINING CLAIM.

The word 'improvements' as used in the United States statute, requiring the making of certain annual improvements on a mining claim, was held to mean such an artificial change of the physical conditions of the earth in, upon, or so reasonably near a mining claim as to evidence a design to discover mineral therein or to facilitate its extraction, and in all cases the alteration must reasonably be permanent in character.

Fredricks v. Klauser, (Ore.) 96 Pac. 679, July ’08.

Catalogues Received.

The Western Electric Co. has just published a small booklet on lead-covered telephone cables.

The Western Electric Co. has lately published its Bulletin No. 5910-8 on electrical equipment of mines.

The C. H. Shaw Pneumatic Tool Co., Denver, is distributing its Bulletin F, describing its No. 8 slugger drill for stopping work.

The Stromhauser-Carlson Telephone Mfg. Co., Rochester, N. Y., is prepared to distribute copies of its bulletin describing the Mine-A-Phone system.

The Cyclone Drill Co., Orrville, Ohio, has recently issued its Bulletin No. 11, which is a description and price-list of the different types of its No. 10 machine.

The Goodman Mfg. Co., Chicago, has issued, under date of September, 1908, its Bulletin No. 101, which describes and illustrates the Goodman chain breast machine for coal mining.

The Bird-Archer Co., New York, is distributing a comprehensive statement of the advantages in using its line of boiler compounds. The pamphlet is called 'Boiler Troubles.'

The Stromhauser-Carlson Telephone Mfg. Co. has recently published its Bulletin No. 1000, on mine telephones. This pamphlet is the first of a series which will eventually illustrate and describe its entire line.

The Killbourne & Jacobs Mfg. Co., Columbus, Ohio, has lately issued a folding circular describing its line of pressed steel and riveted utensils, which includes ore baskets and utensils that may be used around mines and smelters.

The Joshua Henry Iron Works, San Francisco, has lately published its Bulletin No. 111 on hydraulic gravel elevators and water lifters. It contains much valuable information on the duty of the miner's inch and the loss of head, due to friction, in the flow of water through pipes.

The American Spiral Pipe Works, Chicago, has recently published its Catalogue No. 5, which is a handomely printed and elaborately illustrated description and price-list of its line of spiral riveted pipe and forged steel flanges. The pages are replete with complete dimensions of and full information about all the regular and special appliances of this well known firm. A number of tables of useful information adds to the attractiveness of the book.

Commercial Paragraphs.

The National Wood Pipe Co., Los Angeles, received a diploma of award from the New Mexico Territorial Fair, recently held at Albuquerque, for the best exhibit of wood pipe for city water works, irrigating systems, and power plants.

Chalmers & Williams, Chicago, report a contract recently closed for a 20-stamp mill, including two sectional tube-mill and two sectional 36-in. by 26-ft. Burt filters, for shipment to the El Payor mine, owned by McKeevev Bros., of New York.

A plant for demonstrating the Hendrix Electro-Chemical System as applied to gold ores has recently been opened at 605 Howard street, San Francisco. The apparatus consists of a combination of amalgamated plates and mercury ruffles, the latter of special design. Hung above the plates and suspended as haffle-boards in the ruffles, are thin strips of graphite. To the pulp is added a minute amount of soluble mercury salt, which is electrolyzed in passing over the amalgamator. The mercury is thereby precipitated in the pulp, by a current of from 2 to 15 amperes at a pressure of from 5 to 10 volts, the plates and the mercury in the cells acting as the cathodes and the graphite strips as the anodes. The working costs are low, and recoveries of over 95% have been made on suitable ores, and a nearly complete extraction of gold from black sands.
EDITORIAL.

OME'S production of gold for the season just ended is estimated at $5,000,000, which is $1,500,000 less than it was in 1907. Several dumps remain unflushed for lack of water, the precipitation this year having been scant.

A CALL has been issued for the eleventh annual session of the American Mining Congress, which will meet at Pittsburg on December 2. Among the subjects to be discussed are the Bureau of Mines, the Forest Reserve, mine accidents, and smelter rates.

COPPER STOCKS are booming. Since the panie of a year ago the shares of the leading copper-mining companies exhibit an aggregate increase in market valuation of $350,000,000. Amalgamated alone shows a rise of $75,000,000. Utah Copper has appreciated $25,000,000, and Nevada Consolidated, $16,000,000.

FROM AN ACCOUNT of the life of C. W. Morse, the promoter of the ice trust, recently sentenced to 15 years in a Federal prison, we learn that he was a director of 25 companies, including 5 banks and 2 trust companies. What an absurdity it is to suppose that any man can be responsible, as a trustee, for the proper administration of 25 companies. It would be well if no man could legally be a director of more than one bank or trust company. The trusteeship involved should not be allowed to degenerate into a fiction.

BY REQUEST of Mr. Gifford Pinchot, the president of the American Mining Congress has appointed a committee to investigate the effect of the National Forest Service upon the mining industry. The committee appointed by Mr. J. H. Richards consists of Messrs. A. G. Brownlee, E. A. Colburn, W. F. R. Mills, W. P. Daniels, and George J. Bancroft. Our readers are invited to transmit such information as may guide the committee in coming to a conclusion concerning the alleged interference with legitimate prospecting or any other form of mining. Such communications should be addressed to the Forest Reserve Committee at 1510 Court Place, Denver.

WHILE the work of the Forest Service is appreciated by us, it seems proper to protest against the deluge of literature sent broadcast through the mail at the expense of the Government. For instance, we have just received a circular announcing recent appointments in the service of the National Forests. This is waste of money. The appointments are not important, and the announcement of them in this way is unnecessary. The Forest
Service will get into disrepute unless it evinces some appreciation of thrift. National thrift in the preservation of the forests is laudable, but the thrift of the Foresters might well begin by less squandering of wood pulp in needless circularization.

BY THE ELECTION of Mr. Richard C. McLauren as president, the Massachusetts Institute of Technology has chosen an eminent scholar and a strong chief. He is a man of broad training and wide scientific attainment, with a first-hand knowledge of the educational systems of England, Germany, France, Australia, and America. We are informed that Kelvin thought highly of Mr. McLauren; he comes from an old family famous in the intellectual annals of Scotland, he has a large store of energy and business ability. The Tech. has been a notable incubator of first-rate engineers; may it prosper exceedingly.

MENTION was made, in a recent conversation with a smelter manager, of the scarcity of young men serving an apprenticeship in fire metallurgy. Cyanidation and wet concentration appear to be the vogue among the juniors, to the neglect of the older branch of the subject. We asked for the cause of this, and were told that the young fellows liked to go into the cyanide mills and concentrators because it enabled them to be near the mines; moreover, the number of enterprises using wet methods afforded a fairly good assurance of gaining an experience that could be made available in the future. In smelting, it is realized that the number of plants is limited, and most of them are controlled by one or two big corporations, managed by executive committees. The young men in the profession have an idea that promotion with the smelter trust, and its competitors also, goes by favor, and that tenure of position is, at best, precarious. Also, it is held that the advisory experts get the credit for good work, while the local manager is saddled with the blame of any blunder. For these reasons employment with the Guggenheims and other combinations is not as popular as it used to be. We state the facts as we get them, without prejudice. The expression of a contrary opinion will be welcomed.

Francis J. Heney.

Telegraphic dispatches will have informed our readers in the most distant mining regions that Francis J. Heney was shot while doing his duty in court. Some of our readers in Australia and Africa will want to know who Heney is. We shall tell them: Francis J. Heney is a fearless advocate who gave his professional services to Mr. Rudolph Spreckels when that public-spirited citizen came to the rescue of a municipality controlled by thieves. Heney became assistant to the District Attorney. He gave his time and his talents to the cause of the people without payment. He has been outspoken against the bribery of municipal officers by the tramway, gas, and telephone companies; he has fought against the throttling grasp of the Southern Pacific; he has insisted that the man who bribes is as base as the man who is bribed; he has emphasized the greater responsibility of rich and educated men as compared to that of the cheap tools elected to office by predatory corporations. Heney was formerly a student in the University of California, but he has a manhood such as the frontier develops; he is rough in some ways, lacking in culture in others; he is not as polished as Depew nor so tactful as Foraker, but he is gloriously belligerent and splendidly incorruptible. Straight, fearless, honest, he is the kind of man San Francisco has needed and will need; he is the kind of man America may be proud of producing. We pray that he may be spared for a long and useful life.

State Mining Bureau.

Reference was made recently in these columns to the mismanagement of the State Mining Bureau. Several persons have called our attention to an article on 'California Gold Dredging' by Lewis A. Aubury, State Mineralogist, appearing in the current issue of The Pacific Miner. We were inclined to believe that the article was published without the supposititious author's consent, for the middle initial is wrong; moreover, in the preceding issue of the same monthly periodical there was an article on 'Prospecting and Mining Gold Placers', by J. Power Hutchins. We learn from Mr. Hutchins that he did not contribute this article, and that it was taken bockily, without any sort of acknowledgment, from a bulletin published many months ago by the United States Geological Survey. On the whole, Mr. Aubury's article, in whatever way it reached The Miner, has found a fit resting place. The article as published is merely a reprint from a bulletin issued by the State Mining Bureau in May, 1905—three and a half years ago. It was not written by Aubury, nor was it written by J. E. Doolittle, whose name was attached to it when issued by the Bureau. The late Doolittle was at that time a trustee of the Bureau, and aspired to be known as an author on mining topics. But he did not write the treatise on dredging; nor did Aubury. The work was done by the late John D. McGillivray. Not one of the 'assistants' named by the State Mineralogist in his letter of transmittal did any more than Doolittle himself. The entire manuscript was prepared by McGillivray; he was probably told to interview Doolittle on the subject of the early history of dredging in California and this constituted the sum of Doolittle's share in the preparation of the bulletin. The Bureau paid McGillivray's salary and traveling expenses, proving that he did the work for the Bureau, although he was not properly credited. These facts are well known to the men engaged in dredging in California. The publication of this article in the Miner seems so foolish as to warrant the idea that it was done without Aubury's knowledge, but the plates used as illustrations are those appearing in the bulletin, and an editorial puff in the same issue of the Miner is also significant. However, we must assume that neither the supposititious author nor the supposed editor read the article for which they are jointly made responsible. The bulletin was written
in 1904, and the latest statistics quoted are those of 1903. It is a painful anachronism. We are informed that "it is proposed to build a dredge at Folsom with buckets of 13 cubic feet capacity". Several dredges with buckets of this size have been in operation for more than two years past. Other statements of an equally misleading character appear. The author states: "I purchased some of the land through Mr. Hammon," and "I suggested the Feather River gravel and with Mr. Hammon purchased 1000 acres." Of course, we know that although Aubury's name is given to the article, these statements were made by Doolittle, who was a promoter of dredging schemes, but they illustrate the weird mixture of stupidity and misrepresentation involved in the publication of the article as it appears in the Miner. Presumably the author and the editor responsible for this farce are what the daily papers would label 'savants'.

Responsibility of the Press.

On Friday afternoon, November 13, Francis J. Heney, Assistant District Attorney for the City and County of San Francisco, was shot by an ex-convict who had been in a jury impaneled to try a case against Abraham Ruef. The assassin was shown to be unfit to serve as a juror after he had been temporarily accepted, and the exposure had preyed upon his mind so that he attempted to kill the officer of the law who, in the exercise of duty, had been compelled to lay bare his past career. The shot that felled a brave and fearless prosessor startled the sleeping conscience of San Francisco and excited a tremendous expression of public opinion. The significant feature of that expression of public opinion was, and is, the recognition of the fact that behind the act of a crazed individual, behind the failure of justice in this community, behind the contempt of law shown alike by poor ruffians and rich gentlemen, is a debauched press. New York has its yellow journals, such as Pulitzer's World and Hearst's American; Denver lives under the curse of the Evening Post and a weakly daily called the Republican; but San Francisco, of all communities speaking the English language, is afflicted with the bubonic rats of journalism—rats that infect the body politic with the filthy diseases of lying and corruption. The newspapers of San Francisco are owned by men without character and edited by men without principle. We say this without malice. Further, while the punishment of graft has been hindered by the opposition of the Examiner and the Chronicle, it is a regrettable fact that the cause of reform has been handicapped by the methods employed by the papers on the other side. Any just cause must suffer by the activities of the Bulletin and the vagaries of the Call. We remember that both those supposed champions of decency made a violent attack on the jurors who voted for the acquittal of Glass in the first trial, when the evidence was incomplete. This is as indecent and improper an action as a newspaper could take. Even today the Call publishes cartoons scarcely less vile than the Examiner. Reform cannot be proud of its newspaper advocates. This is not the opinion of a soured indi-

vidual; it is the conviction of thousands of educated and professional men in this community. It has been said that a people generally gets the kind of government it deserves; is it true that a community is usually served by newspapers of a quality like unto itself? We hope not. We know of cities that have papers far ahead of the average intelligence and character of its citizens; such papers lead; such papers educate and uplift, more effectively than a university. At a time when Hearst has proved the power for evil of a prostituted press, we are glad to emphasize the fact that America has many splendid newspapers, and those newspapers are the basis of profitable business. The Evening Post of New York, the Boston Transcript, the Springfield Republican, the Baltimore Sun, the Chicago Daily News, the Portland Oregonian are great influencers for good, and they are also profitable enterprises. No such newspaper exists in San Francisco.

At the mass meetings of citizens held during the past week there has been voiced an intense detestation of the subsidized press. It is believed that the daily poison of innuendo and slander has not only obstructed justice by tending to belittle the officers of the law, but it has driven ignorant men to such crimes as the attempt to kill Gallagher, the pivotal witness in many cases now pending, and it has culminated in the attempted assassination of Mr. Heney. Assuredly, journalism has never fallen so low as in the case of the Oakland Tribune, a paper so disreputable that anything it says about anything is of no consequence; or of the Wasp, which gets its sting from the manure pile. For the Argonaut there is no excuse; the editor of that famous periodical ought to know better, but he does not. He can imagine that no rich and successful "gentleman" can do wrong, and he harps on the vulgarity of a hero like Heney until his own vulgarity sickens the reader. His predecessor, Frank Pixley, sold himself to the Southern Pacific Railway company like a bushel of potatoes, and while the present editor of the Argonaut is, of course, above common bribery, he is obsessed with a mental snobbishness nearly as contemptible and quite as effective in the support of wrong. And all this is said by one who is not involved in any local quarrels, whether of business or politics; it is said by a sympathetic spectator, who loves and respects the fundamental principles of American civilization and is heart and soul in the fight for the betterment of representative government.

We do not write bitterly without warrant nor, we hope, uselessly. It is high time for the American people to recognize that the daily press has a power wholly out of proportion to the character or intelligence of the men that control it. The harm done by Hearst with his seven literary sewers every day in various cities of this country is inestimable; we regret to think that it is more potent for evil than the power for good exercised by the three or four able and forceful newspapers already mentioned. The clean papers are read by the few; the yellow journals are read by the many. By caricaturing honest men, by cartoons suggesting violence, by insid-
ions teaching that inflames weak minds, by these
devices the murderer of McKinley was taught, by
these devices the assassin of Heney was promptcd.
And if the Hearst papers are bad, even worse are
such papers as the Chronicle, which publishes editor-
ials full of indirection while its news columns are
sold to the highest bidder. Men who may skip an
editorial will read the news of the day, not knowing
that it is inaccurate, if not deliberately falsified. The
same is true elsewhere; of this tragic comedy it can be
said: Time: Present. Place: Any large city in
America. For the last two years the courts of this
City have been occupied in trying men indicted for
crimes of a fundamentally dangerous character, such
as corruption of officials, bribery of jurors, assaults
upon witnesses. Every case has been tried in the
papers, in every instance a verdict has been given
by the editors, in every instance the minds of the
people—and especially of possible jurors—have been
prejudiced, weeks before the case has been called
in court. There is not an editor of a daily paper in this
City who should not have been hailed before a
Judge for contempt of court. To the press of San
Francisco must be laid the blame for the miscarriage
of justice and the discredit of judicial procedure.

Postal Facilities.

Efforts are being made to improve postal com-
muication with the mining settlements in the North.
The Canadian post-office department has announced
that the list of matter transmittable to the Yukon
during the coming winter has been enlarged so that
the only matter now excluded is newspapers and
periodicals that are sent as samples or for trade, all
papers intended for bona fide subscribers being ac-
cepted at third-class rates. In Alaska the Ameri-
can Government has made arrangements that will
greatly improve the postal service, especially be-
tween Valdez and Fairbanks, which is the trunk
line to the 'inside.' Last winter there was a delivery
twice each week; this winter there will be 20 addi-
tional round trips with an average load of 500
pounds per trip, so that in effect there will be a tri-
weekly service. Moreover, the post-office depart-
ment has contracted for the movement of 32,000
pounds more from November 24 to April 8, so that
this provision is made for the better portion of the
newspaper and magazine mail. This winter service will
supersede communication by river-steamers, and, as
a matter of fact, the mail delivery will be more fre-
quent and more regular. The steamers do not run
on schedule time, they are delayed while waiting for
freight, and they miss connection, so that in summer
it is not unusual for 20 days to be consumed in the
passage of mail from San Francisco or Seattle to
Fairbanks. In winter, delivery is assured within
12 to 14 days. Between Eagle and Gibbon, where the
Tanana river enters the Yukon, the mail will be
carried each way every two weeks between October
and May. The total weight on each journey being
limited to 400 pounds. From Eagle, down the Yu-
kon, across the cut-off at Kaltag, to St. Michael, and
thence to Nome, the postal service will be performed
by the aid of dog-sleds, necessitating a limitation to
the load transported, but it has been arranged to
give better service than last winter by permitting
not only all the first-class but also a large part of
the second and third-class matter to be carried to the
people exiled on the Seward Peninsula. Last winter
the contract with the mail-carriers made provision
for the delivery of 500 pounds per week; this year
an additional weight of 6400 pounds is to be trans-
ported from December 10 to March 91, in 16 weekly
trips, so that the increase amounts to 400 pounds per
week or 50 per cent more. Last winter the arrange-
ments provided for the delivery of letter mail and
only a small portion of the second-class matter
offered, but this winter the extra contract is expected
to cover a considerable portion of the second-class
matter and magazines. It may be explained that in
regions where the mail delivery is limited, the pre-
ference is given to letters, and even the affixing
of extra postage to bring newspapers or magazines
within the rank of first-class matter will not ensure
delivery, for the distinction is not as between first
and second-class postage, but as between manuscript
and printed periodicals. After letters, the first
preference is given to newspapers and magazines in
single wrappers sent by publishers to bona fide sub-
scribers. When provision has been made for these,
then the newspapers and periodicals mailed by indi-
viduals to friends are accepted. Lastly come sample
copies, catalogues, and the like, all of which at pre-
cent have no chance to get 'inside' during the winter
of the North. Incidentally, it may be explained that
the interior of Alaska, meaning the country north
and west of the coast range, is called the 'inside,' in
distinction to the rest of the world on the 'outs
side.' We hope to see that distinction gradually
softened until it becomes merely a sentimental diffe-
rence. Better transportation and quicker mail deli-
very will be the extinguishers of this geographical
bias. To those not familiar with this part of the
American continent it is well to state that the dis-
tance from San Francisco to Dawson is 2374 miles,
from Dawson to Gibbon it is 700 miles further, and
from Gibbon to Nome the distance is 1000 miles.
From Seattle to Valdez it is 1423 miles, and from
Valdez to Fairbanks, over the winter trail, the dis-
tance is 352 miles. If anything can conduce to
making the hinterland of Alaska seem less like a
"non-contiguous" possession of the United States, it
is improvement in the postal service.

THE SIMPLYFIDE Spelling Bored is at it again.
The members of that board cannot be more so
than we are. Their antics provoke in us a feeling of
extreme lassitude. According to a recent statement,
these reformers of spelling are proud of the fact that
their simplified spellings appear in magazine adver-
tisements, booklets of real estate men, circulars of
brokers, and so forth. This they deem encouraging!
We can testify frankly that when a contributor to
this journal shows signs of simplification—by muti-
lation—of his spelling, we find his matter verbose,
badly constructed, undesirable.
**Personal.**

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

LEWIS T. WRIGHT is at Salt Lake.

J. R. FINLAX is at Golconda, Nevada.

LEONEL LINDSAY has arrived in San Francisco from Colorado.

A. N. ROGERS is in charge of the North Star mine, Arizona.

W. H. WELD is at Los Angeles, and is going to Globe, Arizona.

H. L. BROWN is superintendent of the Clara Consolidated Co., at Bisbee, Arizona.

GEORGE W. WILKINS sails from New York for British Guiana on November 22.

NAT P. WILSON, of Denver, is manager of El Puyur mine at Parrell, Mexico.

ELTON W. WALK is superintendent for the Tombstone Con. Mines Co. in Arizona.

ARTHUR S. WRIGHT was in San Francisco and is now on his way to Salida, Colorado.

J. H. HUTCHINSON, metallurgist with the Goldfield Consolidated, is in San Francisco.

R. B. HUTCHINSON is manager for the Rio Tinto Copper Co., operating at Terrazon, Mexico.

G. C. KLUG has resigned as manager for the Phillips River Gold & Copper Co., Western Australia.

S. E. BRETHOUR is in southern California and is expected in San Francisco on November 20.

H. C. HOOVER is expected in San Francisco in December.

H. E. WATSON was recently at Cobalt, Ontario.

BARLETT L. THANE, superintendent of the Eagle River Mining Co., Alaska, is at Berkeley, California.

J. H. FENWELL is now at the Poderosa mine, in the south of Spain, belonging to the United Alkali Company.

F. W. LINTER is visiting London, after having spent some time in the Ural mountains for the Platinum Corporation.

CLAUDE VINTIN is visiting London. He is associated with several metallurgical enterprises in South America.

EUGENE P. KENNEY, assistant superintendent of the Alaska-Treadwell mine, is visiting his home in San Francisco.

G. A. R. LEWIS, consulting engineer to the N. A. T. & T. Co., at Dawson, is spending the winter in San Francisco.

S. S. LANG, formerly with the Benito Juarez mines, in San Luis Potosi, Mexico, is engaged in geological work in Chihuahua.

H. J. BARON, former associate editor of *Mining Science*, Denver, Colo., is manager of the Mexican Chemical Co., Chihuahua, Mexico.

BERT PETERSON, manager of the El Rey mine and mill, Santa Barbara, Mexico, has returned from New York and other Eastern cities.

FRED BURNS, formerly at the Alaska-Treadwell, has accepted a position for the South American Mines Development Co., in Ecuador.

JAMES HANNA, formerly with the North Butte Co. at Butte, has accepted the position of general superintendent for the Austin-Manhattan Co. Company.

**Obituary.**

ALEX DROG was killed on October 11 in the Frost shaft of the Austin-Manhattan Co. Co., at Austin, Nevada. Mr. Droog was 67 years of age, a native of Scotland, and was well known throughout Nevada as a mining captain of great ability. He sunk the Frost shaft years ago, and was cleaning it out and re-lumbering it for the above Company, when a sudden rush of fowl air caused his untimely death.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Walker & Meyers have bonded their Black Queen group of 11 claims to F. S. Hayward and Herbert Hausman, who have already started a force of three men at work in crosscut from an adit on the Black Queen claim. No cash payment was made and none is due until 11 months from the date of the contract. The group is one and a half miles east of Paradise.—Miners bring the news of a new gold excitement near Gleason, which has aroused much interest and caused quite a rush to the new fields. Some rich samples of free gold were found, and further work has encouraged the belief that a rich goldfield has been found. The country is all located by the prospectors and miners who were attracted from Gleason, Leadville, and Courtland, and it is thought development will open up a bonanza.

The Warren mine near Bisbee has shut down, probably because of lack of funds to carry on the work, although some rumors have it that excessive water was the cause.

MARICOPA COUNTY.

(Special Correspondence).—Indications point to much mining activity in the long neglected White Tanks district, 35 miles west of Phoenix, during the coming winter. At this time the largest force of miners in the district is at the Union property. This mine is developed with several vertical shafts, the main one of which is 230 ft. deep, with levels run out upon the vein at intervals of 50 ft. to the extent of about 250 ft., making almost 500 ft. of development work in this shaft alone. The work is in ore all the way down and all the drifts are in ore of a milling grade. The vein averages about 20 ft. wide between walls, and the pay streak varies from 3 to 8 ft. wide. The main vein is a true fissure in granite, the fissure being filled with diorite and porphyry dikes, which act as a hanging wall for the gold quartz vein, which carries the ore. There are several other mines and prospects in the vicinity of the Union mine whose ore averages over $18 per ton. The Black Hawk Co.’s property, one-half mile west, is developed with a shaft 80 ft. deep, the ore of which milled $18 per ton. There is also the National mine, one mile north-west, which is producing ore that mills $16 per ton. There are several other gold prospects in the district being operated by the owners without the employment of outside labor. The district is in the gold belt that runs northeast to Fair Peaks and southwest to the Vulture mine at Wickenburg. Plans are being made by the owners of at least two of the properties above named to install steam hoisting plants, and, if possible, to erect a mill for the reduction and treatment of all the ores in the camp. In the latter enterprise outside capital will be asked. The ores of the camp are a thoroughly oxidized quartz, and the gold is absolutely free-milling.

Phoenix, November 14.

MOHAVE COUNTY.

A strike of rich ore was made last week on the 700-ft. level of the Billy Bryan mine in the Gold Road group. The shaft has been going down for the last six months, but now a station is being cut and a level will be started at this point. A drift being driven from the 500-ft. point of the Gold Road shaft to strike the Billy Bryan has only 100 ft. farther to go.—A station is being cut at the 500-ft. level of the Golden Gem shaft, at Cerbat. Drifts are to be run in several directions and it is expected that good orebodies will be developed.

TAYAPAII COUNTY.

(Special Correspondence).—The properties of the Consolidated Arizona Smelting Co., bankrupt, consisting of a complete smelting plant at Humboldt; a number of valuable mining claims; stocks and bonds were sold today at public auction by the trustee in bankruptcy, J. Kearney Ricketts. The prices accepted aggregating about $400,000 of which amount $200,000 is cash, and the purchasers agree to take over mortgages to the amount of about $260,000. The purchasers are Edwin S. Hooley and Thomas Achenbach, of New York, there being only one other bid, that offered by J. Thomas Reinhardt, which was $600 less than the bid finally accepted. When the sale was announced, the purchasers immediately paid to the trustee in bankruptcy 10% of the purchase price. It seems that there are a number of unsatisfied claims against the bankrupt company, and it is probable that these will have to be adjusted in the courts. It is to be hoped, however, that all claims will be speedily settled and the smelter started, as it means much to this county, where so many mines are producing in a small way, but cannot erect their own smelters, or ship their ores to far-away smelters for treatment.

Prescott, November 10.

YUMA COUNTY.

Reports from the Quartzsite district are to the effect that the Colonial mine, which is a quicksilver proposition, will employ about 40 men. The New York Formosa mine is installing the largest crushing and gold-milling plant in that district. A pipe-line is to be constructed from Quartzsite to the mines, a distance of nine miles. The Success mine is shipping ore. The last caroad netted $2300 and the promoters are much encouraged.

CALIFORNIA.

INTO COUNTY.

(Special Correspondence).—The shaft at the Cerro Gordo has been sent down to the 1100-ft. level and a body of rich silver ore has been cut at that point. During the summer a large quantity of ore was developed in the upper
MINING

The turning ex-Government It going reported E. superintendent. The two veins are fissure contacts containing silver, lead, and zinc. To transport the ore from the mine to the smelter, at Keeler, a 200-ton aerial tramway was recently completed. The Keeler smelter comprises one furnace with a capacity of 150 tons per day. The company also owns excellent water rights at Lone Pine and is erecting an electric power plant at that point. E. O. McGrath is general manager. The Tewoo Mining Co. is shipping about 50 tons of lead ore to the Salt Lake smelters and expects to increase the output about the first of the year. The Gunsight vein was recently recovered on the 600-ft. level. At both the Gunsight and Noonday shafts much development work is going on with satisfactory results. About 75 men are employed. The management is planning to erect a large concentrating plant early in 1909. Under present conditions the ore is hauled by mule-trains to the T. T. & railroad. J. H. Lester is manager.—The shaft at the Bishop Creek mine is going down steadily on a vein that assays about $150 per ton. The property is capitalized at $25,000,000, a circumstance that has invited much criticism. To pay dividends this property must naturally develop into a stupendous producer, and at the present time in its present state of development is a financial proposition worthy of Wisconsin’s Magazine and a noted socialist leader, is at the head of the enterprise. Associated with him are a number of American and English Socialists. The mine is at an altitude of about 9000 ft. and during the winter season all work must necessarily be performed under shelter. Prospecting has been done with diamond-drills and several holes in fair-grade ore struck at a depth of several hundred feet. The shaft is being sunk as a result of these bournes. Water-power for all purposes is available.—Some rich ore has been struck in the bottom of a 40-ft. shaft at the Black canyon. A large quantity of milling ore, which assays $10 to $20 per ton, has been developed in the mine. Local people are interested.—The Southern Belle mill is running on ore from near the 25-ft. level of the Bullion shaft. Extensive development work is needed by the company for the past summer were indefinitely postponed owing to the financial depression. San Francisco people are interested.—The 10-stamp mill at the Skidoo mine is reported to be turning out about $10,000 per month, with considerable development work going on in the mine.—The Killian M. Co. is sinking a shaft at its property near Genesee and erecting buildings and cottages. Fifteen men are employed.

Bishop, November 6.

NEVADA COUNTY.

(Special Correspondence).—Thirty stamps are dropping at the Empire and before the end of the month it is expected to have the full mill running. Nearly all the men have gone back to work on full time. The water situation has improved during the past few weeks. George W. Starr is manager.—A 2½-ft. vein of high-grade ore has been struck on the 1400-ft. level of the Pennsylvania mine. Bennett Opie is superintendent.—The North Star Mines Co. is constructing a pipe-line to connect the air-blower at Larimer’s dam with the Central cyanide plant. A rich streak of quartz has been opened on the Beth vein at the Yellow Metal mine. Al Keller and Alex McHill are developing the property. R. M. Wilson, representing the field capital, is inspecting properties at Grass Valley. The St. Gotard G. M. Co., operating the Delhi mine at Columbia hill, has declared dividend No. 4 of five cents per share. The amount is $5000. Active developments are being pushed with excellent results.—The Oustomah and Murchie mines have resumed operations.—It is understood that an assay of $20,000 has been made for the Champion mine, but that it was declared by the owners.

Grass Valley, November 16.

PLUMAS COUNTY.

A strike of $30 ore has been made in the Gruss mine near Genesee. A body of $10 ore, four feet wide, has also been opened at another place. It is said that machine drills and compressors will be put in.—The old Crescent mine, near Crescent Mills, is to be reopened by the heirs of James McDonald. The property has been idle for a number of years because the ownership was invested in an estate.

SIERRA COUNTY.

The case of the United States v. the Mountain Copper Co., of California, brought by the Government to obtain an injunction against the Company, prohibiting it from operating the smelter at Keswick, because of the injurious effects of the fumes to adjacent timber lands, was dismissed last week in the Supreme Court on the ground of stipulation between the Government and the Company. The terms of the stipulation are believed to be that the Company will pay damages done to Government timber, which, by the way, it has always been willing to do.

SIERRA COUNTY.

Robert H. Durfee, who was operating at Poker Flat, has ceased operations for the winter and gone to San Francisco. Mr. Durfee expects to return early in the spring and continue development work on his vein.—Jason Frye and associates have taken a bond on the Cruttenclam in Sailor ravine and will soon start two shifts at work. They plan to drive an adit to strike the vein and then, if feasible, mill the ore. A large quantity of free gold and silver are found in the black sand, and special under-currents are being installed for the purpose of saving that valuable mineral.

TOMALINE COUNTY.

The Imperial group of mines, containing seven claims, at Jacksonville, have been bonded by Charles A. Fitzgerald to the Imperial Co. for $25,000, final payment to be made before January 1910.—John Voss has given an option to purchase at $2500 on his placer property, at Yankee hill, to E. R. McLeod, of Portland, Oregon. Mr. McLeod agrees to furnish hydraulicking machinery and test the gravel.—The shaft at the Ralph mine is now 200 ft. deep and 16 men are employed in sinking still deeper. It is reported that four good veins have been cut by the Bagdad Chase Co.—An air-compressor and power-drills are being installed at the Riverside, above Columbus.—A carload of machinery for the Ethel, two miles east of Columbia, arrived in Sonora last week.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A two-foot vein of 200-oz. silver ore has been opened in the drift from the La Plata adit of the White Metal property on Democrat Mtn. In addition, a 4-in. streak, which assays 1000 oz., is exposed the full length of the drift. This property is being operated under lease by Broad & Woodrow.—In the district there is much activity. On Wood Mtn., the Wood Creek & William Fork M. M. T. & D. Co. is employing a force of eight men in the driving of the adit for the purpose of completing the series of 78 veins controlled. The ore is near the 400-ft. point, three veins having been intersected, but no driving will be done until greater depth is attained. T. Tyler, who is manager, recently sent in supplies to last through the winter months.—Bill Young, the father of the district and owner of the Puzzler mine, is carrying on an energetic campaign for development. During the summer months regular shipments were sent out, the product being shipped direct to the Argo smelter.

Returns averaging
$200 per ton were received in gold and silver, with the former predominating. The lower cross-cut recently intersected the Puzzler vein and a streak of ore was exposed that is 18 in. wide. Driving is now in progress.—G. Dalgleish is driving the Scotia adit and occasional bounches of ore are found which probably contain 50% of gold and silver with a high grade of gold content as high as $900 per ton. A cross-cut will be intersected within a few feet.—E. M. Moser, manager of the Butler mine, is employing a force of men in the development work. A streak of medium-grade ore is being followed but pending the completion of the concentrating plant, now in the course of construction, only dead work is being done. The ore will probably be completed within the next few days.—Nels Anderson, leasing on the Seven-Thirty, has made a shipment of five tons that milled 557 oz. silver and 26% lead. This operator has the best paying lease in the district and during the last three months has been netting from $8000 to $10,000 per month after paying cost of transportation, smelting, and royalty.—Another shipment of 100 tons of silver-lead-zinc ore was started this week from the Gabreltta, Republican Mnt. The ore is being sent to the Linn mill for concentration in order to avoid the penalty on zinc. B. J. O'Connell, who is manager, sent to the sampler 30 tons of zinc ore, which will run nearly 75%. It is the intention of those interested in the property to shortly start another adit, the portal of which will be farther down the hill. With depth the ore-shoots of this locality carry a larger percentage of lead and iron and zinc very soon will be found. Within two weeks a big campaign of development will be put under way upon the Smuggler, Brown Mnt. A new company is now being organized, the property having been purchased from the estate of B. C. Catren for a consideration of $50,000. In addition to the running of the drifts east and west on the five levels, the shaft is to be deepened 150 ft.—Advices received from Nils Anderson, leasing the字体由公司提供.

The ore has been sunk to a depth of 500 ft. and 100 tons of ore are delivered to the mill daily and for the present the ore is hoisted by windlass and then trammed out to the shaft. The management will shortly install a hoist on the winze.—A letter from the Laura Lee claim on Mill hill, covering a period of two years from date has been secured by Ellis F. Britton, of Cripple Creek, from the owners, F. J. Campbell and G. S. Wood, of Deaver. The shaft, already sunk to a depth of 120 ft., is to be carried down an additional 200 ft. with the least possible delay, and a powerful plant of machinery will soon replace the horse-whim now in use. Two heavily mineralized dikes have already been exposed by surface workings on the Laura Lee, and rich quartz containing native gold has been a common occurrence along these Intrusions.—The suit between the Jennie Sample G. M. Co. and Mrs. J. D. O. in which the former sought to recover damages for alleged illegal extraction of ore from the Ophir mine, has been settled out of court by the payment of the Jennie Sample company of $20,000 and the granting to it of the right to use the north and west shafts of the mine for a period of five years.—By agreement entered into between the Peoples M. M. Co. and William Ful- lerton the trust deed in favor of Central Consolidated Mines corporation, the first named corporation, in consideration of $1000, agrees to release all claims to the two acres in conflict between the Gold Leaf lode and the Happy Year and Josephine lode mining claims owned by the Central Consolidated company. The properties are on the northwestern slope of Raven hill.

MINING AND SCIENTIFIC PRESS
November 21, 1908.

GILPIN COUNTY.

Denver people are associated with Joseph Espel, of Central City, in the opening of the Nation No. 9 and Topjoy properties on Michigan hill, in the Pine Creek district. Work is being centered in the National adit, which is now in a distance of 75 ft. Some extra hard rock is being encountered.—Sinking operations have been suspended on the Bench mine. In Russell district, operated by the Aztec Mines Co. at a depth of 200 ft., and now drifts are being extended east and west at that depth. The latter work is being done under contract and good headway is being made. There is about three feet of vein matter in sight and H. Irving Jones, the manager, expects to get under the ore shoot at an early date.—The Rails County mine, on Quartz hill, has been started up during the past week under a lease and bond by John F. Shaw and associates of Brookville, Pa. There is a good plant of machinery on the property, and active developments are being outlined by the lessees. The property has been worked steadily for a number of years past, both by the owner, Charles Gaze, as well as by lessees.—The German mine on Quartz hill has been leased and bonded by Cripple Creek Mining Co. to H. H. McVane, from Bishop Matz, of Denver, under an agreement for two years in the sum of $10,000. Some work has already been done in putting the shaft in good shape and drifts are being extended at a depth of 150 ft. This is the present bottom of the shaft, as it is filled in below that depth, although the shaft is reported to be over 600 ft. deep. The lessee has discovered some uranium ores and has taken hold of the property with the express purpose of developing the uranium orebody. Development work will be carried on and if the indications warrant it the lessee will install a large and powerful plant of machinery within the near future.—A plant of machinery is to be installed on the Great Mammotk mine, in the Illinois Central district, by Gordon & Co., who have taken the property under a lease and bond from John Best, of Denver. The lessees report having opened up a body of ore which they can mine with greatly reduced costs.

SAN JUAN COUNTY.

The Animas Power Co. has made connection with the plant of the Telescope Mining Co., in Mill gulch, and the machinery will be started at once. At first one shift only will be employed. H. A. Miller is manager.—The management of the Champion is asking for bids for an 85-ton adit, to be started at the base of the mountain.—A. L. Klinsen, who is working the Blackstone in Prospect gulch, near the Henrietta, has lately struck an 18-in. streak of lead carbonate. The orebody was found in driving from the bottom of the shaft, through which the mine was worked more than 20 years ago.

TELLER COUNTY.

The Accident Leasing Co., whose promoters and shareholders purchased the Morrel & Bombée lease on the Accident mine on the southwestern slope of Gold hill, at Cripple Creek, commenced hoisting ore last week and will make its initial shipment soon. The leasing company is operating a small hoist at the bottom of the ore shaft and winding down 280 ft. for the present as the ore is hoisted by windlass and then trammed out to the shaft. The management will shortly install a hoist on the winze.—A new lease on the Laura Lee claim on Mineral hill, covering a period of two years from date has been secured by Ellis F. Britton, of Cripple Creek, from the owners, F. J. Campbell and G. S. Wood, of Deaver. The shaft, already sunk to a depth of 120 ft., is to be carried down an additional 200 ft. with the least possible delay, and a powerful plant of machinery will soon replace the horse-whim now in use. Two heavily mineralized dikes have already been exposed by surface workings on the Laura Lee, and rich quartz containing native gold has been a common occurrence along these Intrusions.—The suit between the Jennie Sample G. M. Co. and Mrs. J. D. O. in which the former sought to recover damages for alleged illegal extraction of ore from the Ophir mine, has been settled out of court by the payment of the Jennie Sample company of $20,000 and the granting to it of the right to use the north and west shafts of the mine for a period of five years.—By agreement entered into between the Peoples M. M. Co. and William Fullerton the trust deed in favor of Central Consolidated Mines corporation, the first named corporation, in consideration of $1000, agrees to release all claims to the two acres in conflict between the Gold Leaf lode and the Happy Year and Josephine lode mining claims owned by the Central Consolidated company. The properties are on the northwestern slope of Raven hill.
IDAHO.

KOOTENAI COUNTY.

Uranium has been discovered on the property of the Green Mountain G. M. & M. Co., near Tyson. The ore was discovered in the tunnel known as the Ahlstrom tunnel, and in a parallel, which it was thrown on the dump, where it remained until a miner from the Black Hills recognized it. Assays show the ore carries 3.75% uranium, and is worth $130 per ton. The ore was found in a four-foot vein running 12 ft. south of, and parallel to, the main gold-bearing vein, which has been under treatment several years. It occurs in two forms, a dark-green glossy ore, in fragments, in weight, and also a pitchblende, black and heavy. John A. Johnson, Jr., and associates, of Spokane, are interested.

SHOSHONE COUNTY.

(Special Correspondence).—Still a third suit has been hurled at the Bunker Hill & Sullivan Mining & Concentrating Co. This is at the instance of the January Mining Co., and is for no less than full possession of the great Wardner lead-silver vein, and for a full accounting for all mineral-bearing rock or ore taken from the vein. The January Mining Co. is a corporation organized under the laws of the State of Connecticut, and with its head office at Portland, in that State. It claims to be the assignee of the Republican Fraction claim, in the Yreka mining district, by virtue of a series of transfers through which the claim in question passed from the possession of the Federal company to that company's attorney, Frank T. Post, of Spokane, and from him to the January company. On account of these transfers it is the general belief that the Federal company is in reality behind the suit, the winning of which would probably give them the control of the world lead market. It is alleged in the complaint that the Wardner vein traverses the Republican Fraction claim in an easterly and westerly direction, and that on its course the apex of the vein crosses the end lines of the claim. The downward course of the vein is said to be southerly and on this course passes out of and extends indefinitely beyond a vertical plane drawn through a southerly boundary line. It is also alleged that this vein is the same as that which outcrops within the Bunker Hill. Stemwinder, Last Chance, Emma, and Tyler claims and which is generally known as the Wardner vein or lode. The January company claims to be entitled to the possession of all of the vein throughout its entire length, including that part of it which extends through the claims named. The Bunker Hill company is accused of having converted to its own use all the ore contained in this vein, but to what extent has not been ascertained. It is also alleged that the defendant company is so working within the vein as to destroy the evidence of the value of the ore which it has extracted by filling the voids created with debris and waste. The January company petitions for judgments of $7,000,000, the reputed value of the ore taken from the vein since November 15, 1915; that its title to the Republican Fraction claim and the whole of the Wardner vein be quieted; that the Bunker Hill company be made to account for all mineral-bearing rock or ore extracted from the vein; for the costs of the action; and for general relief. Gray & Knight, of Wallace, and Frank T. Post, of Spokane, are attorneys for the plaintiff company. One of the most important developments in connection with the mining industry of the Coeur d'Alene is the proposition by a number of the biggest owners in the Murray district to develop their properties by means of one long adit and a jointly owned mill at the portal. This project has been mooted for some time past, but steps are being taken at present to bring the proposition down to a business basis. Those who are thoroughly intimate with these plans state that the result will either be the operation of an adit and a mill as stated, or else the formation of one merger including five, at least, of the best mines in the district. From preliminary surveys it is estimated that the adit will be about 7000 ft. long and cost approximately $100,000. If built it will develop a total of 61 claims belonging to the following mines: Jewell, Chicago-London, Black Horse, Paragon, and Bear Top. The portal will be at the Jewell mine, which is on the line of the Idaho-Northern railroad and offers exceptionally good facilities in the way of mill sites.—A splendid impetus to the industry of the whole district has been given by the announcement of the Snowstern Mining Co. of another dividend of $45 per share for the year 1916. The company proponent this dividend is a statement of the management that dividends will be continued at the same rate throughout the year. The company has now disbursed over $1,000,000 in dividends, of which $90,000 has been paid this year. The big 11-ton transformer for the Washington Power Co. has at last been delivered at the company's sub-station at Wardner. The transformer is being used by the Federal company in the working of the Last Chance mine, replacing the two smaller transformers used in the past.—An important decision in favor of the mining companies of the Coeur d'Alene has been rendered by the United States Court of Appeals, at San Francisco, in connection with the suit of Timothy McCarthy, Elmer Doty, and William Raney, on behalf of the ranchers in the Coeur d'Alene valley against the Bunker Hill & Sullivan Mining Co., the Federal Mining & Smelting Co., the Gold Hunter M. & S. Co., and Larson & Greenough. The suit was for a perpetual injunction against the mining companies and was based on the claim that by reason of the water of the Coeur d'Alene river being used for mining purposes it was rendered unfit for irrigation. Forty-five prominent ranchers are represented by the suit and the decision was quite a blow to them.—Steps are being taken to relieve the Rex Mining Co. from the litigation which has hampered the development for several months and under which shipments from the mine were made under supervision of the Court. The mine is a steady producer and is equipped with a 100-ton mill.—Everything is now in readiness for starting the long adit in the Copper King mine. The new stoppinger has been installed and all the newly ordered equipment delivered at the mine. The arrangement of the buildings in this property is said to be the best of any mine in the district, all being connected under one roof. The adit in which work is about to start will cost in the neighborhood of $45,000 and will give a depth of almost 1900 ft. more than the existing lower workings. At the extreme north end of the Mica and Sullivan south copper mine the Coeur d'Alene it was decided to levy an assessment of three mills per share on the capital stock, for the purpose of providing funds with which to further exploit the property by diamond drilling. The secretary-treasurer's report of work for the last year showed that $31,479 had been expended and that but little more than $1000 remained in the treasury. The leases of the property of the Idaho Mining Co., in the Sunset Peak district, have commenced the shipping of ore to the Panhandle smelter, at Sandpoint. The first shipment consisted of 40 tons and others will follow at regular intervals.—A new hoist and pump are to be installed in the property of the Gold Ridge Mining Co., in the St. Joe district. The shaft has been sunk to a depth of 190 ft. and some ore assaying $65 per ton has been found. Wallace, November 14.

NEVADA.

CHURCHILL COUNTY.

Charles Lamb and James R. Keir are planning to continue work all winter on their properties in the Wonder district. They have recently sent a stock of supplies in from Fallon.—The June Wonder is to let a contract for sinking an additional 50 ft. in its shaft.—E. A. Ferron and Harry Grigsby have recently taken a contract for some additional work on the Vulture Extension property.

ESMERALDA COUNTY.

The Goldfield-Boston Mining Co. will resume work on its group in the eastern part of the Goldfield district, and D. W. McFadden has arrived to manage affairs.—The management of the Mussett lease has been compelled to sus-
pend operations because of a lack of funds to meet the payrolls.—Having outlived its usefulness, the Kinkaid mill has been closed. For the past several months it has been used to treat Combination mill concentrate by the Hutchinson process. This process will be used at the new Consolidated mill, and until such time as the new plant is in readiness, the concentrate from the Combination mill will be allowed to accumulate.—A meeting of the shareholders in the Washington-Nevada Mining Co. was held last week in Goldfield and it was decided to sink a shaft to a depth of 100 ft. on one of the claims of the Company east of Lida. C. H. Beesley has been elected president; N. B. Bertram, L. E. Campbell, Robert Lanka, and Louis Switzer are additional directors.

HUMBOLDT COUNTY.

The merger recently reported as consummated between the Seven Troughs, Therien, Kindergarten, and Red Cloud properties is now a fact, and on this merger is based the Seven Troughs Coalition Mines Co. The new Company will add to its holdings some of the other prominent mines of the camp.—G. C. Richards, of Berkeley, California, has been looking over the mining situation at Vernon, in view of the installation of a custom mill at that point.

LINCOLN COUNTY.

Operations are to be started at once by the Searchlight-Spokane M. & M. Co. on its property at Searchlight. The main shaft will be enlarged and then sinking below the 200-ft. level will be undertaken. Pending the installation of a pumping plant, an unexplored portion of the mine to the west below the second level will probably be developed. A. M. Jennings is president.—J. G. Thornburgh, of Colorado, has taken a two years' lease and bond on the Red Bird group, three miles east of Searchlight. By the terms of the contract work must be started by December 1.—H. J. Myers, of Detroit, Michigan, is reported to be interested in a project to build a number of dredges on the Colorado river near Eldorado canyon.

NYE COUNTY.

Three carloads of machinery for the Jefferson mine, near Round Mountain, have arrived at Battle Mountain, from which it will be hauled by wagon. W. H. McBeth has recently purchased the Jefferson and expects to develop a dividend payers.—It is expected that the custom mill at Springdale will be in operation some time in January.—J. V. Priest, manager of the Mogul mining group in the Ray district, ten miles north of Tonopah, expects to leave soon for the East to interest capital in the group of eight claims owned by his company.—The first clean-up of the Goldfield Blue Bell Mining Co. was made last week at its mill on the Stokes property at Berlin. The clean-up amounted to $15,000 and was entirely from ore in the mine and on the dump. The ore ran a little more than $10 per ton. Only 20 of the 30 stamps are in use.—The Tonopah & Goldfield Railroad Co. has decided to transform all their coal-burning engines into oil burners.—The mines of Tonopah produced during the week ending November 14 a total of 5393 tons of an estimated value of $134,825.

WASHINGTON.

(Special Correspondence).—The Lucille Drydys mine, near Danville, is producing richer ore than usual, and some of it contains copper. The company will soon begin shipping. A larger force will be employed, when the winze below the adit level will be sunk 100 ft. deeper.—The Koller & Indiana S. & D. Co. is employing ten 4-horse teams hauling ore from the Manilla mine to the smelter at the rate of 35 tons per day. Over 200 tons have been hauled. Charles Young, formerly of Cedar Canyon, Stevens county, has succeeded Spence Smith as superintendent of the Manilla mine, and a rich strike was made a few weeks ago while cutting out a station on the 300-ft. level of the Leonett mine, on Meadow creek, three miles northwest of Keller. A winze will be sunk at the station. The property is now under bond to Seattle people, who will push development work during the coming winter.—G. Weaver Loper, general manager for the Colville M. & S. Co. has returned to New York, after sending the Independence group of claims, at Park City. The purchase will add five valuable claims to his former purchases. The consideration is stated at $24,000, of which $3000 is cash, the remainder is to be paid in ten months. The tightness of the money market retarded work on the smelter under construction by the Colville M. & S. Co., but work on it is now being rushed.—Recently the Longstreet and R. E. Lee claims in the Enterprise district were bonded to the Dan Patch M. & D. Co. of Spokane, composed of Cowell & Algernon men. The Longstreet is traversed by a porphyry dike, about 100 ft. wide, which carries silver in payable quantities. Some of the ore is very rich. On the R. E. Lee a porphyry dike, about 200 ft. wide, parallels the other and is traversed by a vein of porphyritic quartz, through which streaks of amnonoidal ore, some of it solid stihline, run from two to four feet wide. The R. E. Lee is opened by shaft work and 500 ft. of adit on the vein. The Longstreet is opened by shafts, other surface work and an adit, 200 ft. long, cross-cutting the porphyry dike.—The Silver Leaf mine, under active operation, is situated on Rattlesnake Mtn., one-fourth mile east of the Longstreet. It is under bond to Seattle people. It has an outcrop about 50 ft. wide. At a depth of 75 ft. this vein has been intersected and an adit follows it about 200 ft. These, with considerable surface work serve to show up a fine-looking property. There are about 100 tons of ore on the adit dump. Should the bonds on these properties be taken up, considerable activity is promised, and both Meteor and Covada camps will doubtless become lively. Among the principal mines of the Enterprise district, owned by incorporated companies are the Meteor, Stray Dog (the latter lately passed into new hands, after a long period of internal strife and litigation), Syndicate, Advance, Keystone, Blackborne, Oriol, Southern Cross, Blue Grouse, Perry, Nonpareil, Etta, New York, Cold Spring, and White Swan groups, all having contact veins, mainly between granite and porphyry formations. The Silver Leaf vein lies between granite and limestone, the latter forming the hanging wall. The Stray Dog is a valuable mine, showing gold, silver, copper, and lead ores. The vein crosses Stray Dog canyon, and a group of claims, with a 40 ft. in it, is owned and is under development by George Turpening, who is driving a cross-cut adit to tap the vein 150 ft. deep. This group is called the Imperial. Republican, November 14.

SKAGIT COUNTY.

The Skagit Queen, at Marble mount, is being developed and equipped under the superintendency of C. D. Grove, who has a force of 35 men. An adit is being driven with air-drills to open the orebody, which carries chlorite and bromide of silver, with some gold and copper, in a quartz gangue. A 1500-ft. pipe-line, extending from a point above a dam on Thunder creek to the power plant, gives a 500-ft. head of water. The power plant, when finished according to present plans, will consist of two air-compressors, driven by Pelton wheels. A dynamo will be operated also to generate electric light for the camp.
Special Correspondence.

DAWSON, YUKON.

Close of Season.—Yukon Ditch.—Dredging on Forty-Mile.—Successful Operations.—On the Stewart.—Creek Diggings.—Cheerful Prospects for Next Summer.

This winter in Dawson came suddenly, sooner, and with more severity than usual. We were taken unawares and consequently unprepared, being obliged in some instances to use hot water to thaw out our frozen sluice-boxes in order to make the final clean-up. Of course, the usual perseverance obtained in small things, such as needed parts of machinery that were delayed at White Horse or points farther south, etc.; nevertheless, on the whole, the season has been satisfactory. The output this year will probably exceed $2,500,000, an increase of more than a million over last season. This increase is due to the improved methods of working the low-grade gravel by the use of dredges, mechanical elevators, aided by hydro-electric power. These are the improvements lately installed by the Yukon Gold Co., and consequently they are in a great measure responsible for the increase in our gold output. This company has done a great deal of work this summer, employing at times as many as 2500 men, who have been well housed and cared for—no small undertaking in itself, in this country of big distances and difficult transportation. The greater part of this force has been employed on the big ditch. This ditch, with its connecting pipe-lines, in the form of inverted siphons, spanning the intervening gulches and valleys, is finished, and water could have been turned on this fall, but it was thought best not to soak the bottom of a new ditch just before the freeze-up, because this would have left it in bad condition for early use in the spring. The water will be turned on for the first time next year, then great things are expected, as the hillsides and benches on Bonanza creek, where this water is to be used, are rich. It is expected that this ditch will deliver 5000 inches of water. A particularly fine piece of work in connection with this ditch was the last connecting link in the system; it was the siphon across the Klondike valley at a point opposite Bear creek. It is 44 in. diam. at the lowest point, which is 1100 ft. below the intake, and approximately three miles long; and is probably the largest of its kind. The other siphons belonging to this system are equally good, but do not impress one so much, possibly because they are not nearly so long. At the point of greatest pressure, the pipe is ½ in. thick, lap-welded, and solidly riveted; as the pressure decreases on both sides the thickness of iron is less, accordingly. Wooden pipe is used at both ends until a point is reached where the pressure exceeds 65 lb. per square inch. The whole is firmly secured on substantial trellis work of native timber, and is very strong. C. G. Newton has been in immediate charge of this work.

Four new dredges have been put to work this season by the same Company, with gratifying results. They all have 7½ buckets, two being Marion, and two Bucyrus boats. One of these machines was started on 90 Below on Bonanza, recovering it is said, 60 cents per cubic yard net, and digging 3750 cu. yd. of gravel and bedrock each 24 hr. Another equally good boat was put to work on 35 Below on Hunker creek; returns from this machine have never become known, but we do know that the ground at this point is rich, so no doubt the output was good. The third boat started to work on the upper end of the Anderson Concession late in the season; several clean-ups were made; these were large, but the exact amount could not be obtained; it is safe to say that they exceeded $10,000 for each run of from two to three days. The fourth, and also the last boat to start, was built at the mouth of Hunker creek, but got to work so late that she could do nothing more than dig herself into secure winter quarters. All of these boats should give a good account next year.

The mechanical elevator designed by O. B. Perry demonstrated that it is the most effective piece of machinery yet devised for the recovery of gold in creek-bottoms where it is impossible to work dredges, either on account of heavy bedrock, its depth, its narrowness, or for various other reasons.

The Walker's Fork Gold Dredging Co., of London, started their new dredge to work about the middle of June; this boat was built by the Riedon Iron Works, of San Francisco, and is equipped with a 5-ft. open-connected bucket line, and is of latest Riedon design all through. It is run by steam, as there is no electric power to be had in this district. This boat is now in charge of Robert Milvain, who represents this company in the North.

Many obstacles made it impossible to get down to work until the latter part of the season, but as the ground moved yielded nearly a dollar per yard, there was no disappointment in camp, as it was felt that all difficulties would soon be overcome. Russell Kinz, of London, is president of this company. The Consolidated Gold Dredging Co. of Alaska, with headquarters at Chicago, and local offices in Dawson, is developing a dredging field of great promise on the Forty-Mile river; they control about 40 miles of the river bed, and now have a 7½ ft. open-connected Allis-Chalmers dredge at work, at a point 7 miles upstream from the mouth of the river. This boat is working in the river, the gravel being in almost every case submerged; a cut 200 ft. wide is taken, the gravel varying in depth from one or two feet above bedrock to as much as 16 ft. The gold lies chiefly on, and in, bedrock: it is necessary to dig at least four feet of it to be sure that the extraction is complete. As the bedrock so far has been soft schist, no trouble has been found in digging to this depth. It is understood that the company is making money with this machine, as at the present time the boat is digging through the Sour Dough bar, which was one of the spots that could always be depended upon to furnish a grubstake in the days before Dawson was even thought of. They have also a smaller dredge, which was assembled in Dawson the ma-
The Yukon Basin Gold Dredging Co., of which William Ogilvie, former Governor of the Yukon Territory, is president, succeeded in getting its first dredge to work this summer. It is a small boat, with 9-ft. buckets, and built by the Risdon Iron Works. The company controls about 50 miles of the Stewart river, a tributary of the Yukon, about a hundred miles above Dawson. It is expected that a number of the latest type of dredges will soon be put to work, as the results obtained with the small dredge used this season have been encouraging. I understand that this boat will be used in the future as a prospector, in much the same way as the boat of the Consolidated Gold Dredging Co. It is one of a part of this type of machinery which Frasier falls on the upper Stewart; these falls offer the best chance for generating power in the Klondike region. The Bonanza Basin Gold Dredging Co. owns a valuable property in the Klondike valley; it begins at the mouth of the Klondike river and extends upstream for 1½ miles, and is partly within the townsite of Dawson. Most of it is thawed, which is a tremendous advantage; it is rich, accessible, and easy to work. At the present time they have a 7½-ft. open-connected Allis-Chalmers dredge. This boat was originally a side-discharge machine, a type not at all suited to the conditions; last year it was re-constructed, and now is a regulation stacker type of boat, and this season has done excellent work. A much larger dredge is to be placed on this property, probably a 9-ft. Dycrus. When completed, this will be the last dredge in the Yukon. The Yukon Gold Co. is supposed to have absorbed this company.

Dominion creek, the Granville district, Sulphur, Quartz, Black Hills, and parts of Hunker creek, where mining is still done in the old way, have given a good yield of gold, and more winter work is under way this year than for some time. It is expected that many valuable dumps will be taken up this season, and the company's property known to be rich. Duncan, Haggart, Dublin gulch, and various tributaries of the McQuester river, are also being worked more extensively than in the past and it is hoped that good results will follow. Duncan creek is very deep, being 100 ft. to bedrock, and only partly frozen, making it difficult to work; all prospects so far found indicate that this creek may yet prove rich. The Canadian Government has supplied the miners on this creek with pumps and machinery, which it is hoped will be the means of determining its value; this machinery is not operated by the Government, nor is any financial aid given; the miners must furnish all necessary fuel and labor. From this showing it is evident that next year's output will be larger than this year's, and so it will continue to be for many years to come.

TORTO, CANADA.

Cobalt Boom.—New Companies.—Montreal River.

The Cobalt boom received a stimulus this week from a visit to the mines at the week-end by the members of the Standard Stock & Mining Exchange of Toronto, including representatives of nearly all the companies in this city. They inspected the principal mines in which the public is interested, and were in nearly all cases afforded the fullest facilities to make a close examination. A fact which strongly impressed itself upon the visitors was the great change in methods in the direction of improved equipment and thoroughness of development on a permanent basis, in place of the haphazard and make-shift way of conducting affairs which has been prevalent in the past. The change is undoubtedly due to the evidence that rich ore exists at depth, which has justified and rendered possible heavy expenditures on plant and buildings, and the adoption of policies looking to the future, instead of seeking the largest possible immediate returns. In several instances it was found that mine managers had their work arranged in detail for two years ahead, ore deposits being blocked out without any intention of immediate shipment. In view of the present low price of silver, some of
the companies are disposed to restrict production to an amount sufficient to meet expenses and pay current dividends, holding as much on the market as will cause the output as the market improves. More attention is being paid to the important matter of lessening operating expenses, one of the means adopted to this end being co-operation between different companies in the opening up of veins which extend from one property to another. The rise in Cobalt stocks, which has been steady for some months, has been occasioned by reactions of short duration, has resulted in a large number of new flotations, some of them apparently of the wild-cat species. So many propositions have lately been sprung upon the public that, when the large amounts already invested in companies of acknowledged standing are considered, it is difficult to see where the subscriptions necessary to put them on their feet are to come from, and many of these ventures are likely to be still-born. Among the more promising which have passed the dubious stage so far as obtaining funds is concerned are the Gifford and the Otisse. The former, which, with a low capitalization, was largely over-subscribed, has been followed by the Gifford Extension, promoted by the same interests, on a larger scale. It is capitalized at $350,000, and will develop what has been heretofore known as the Calverly-Wolfe deposits. The Otisse is the result of the numerous Montreal River propositions put on the market, and has been well received. Many other properties in this section are included in the daily lengthening list of new flotations, and there is an increasing interest in this region, which, whatever be the fate of the present ventures appealing to the public, appears likely to divide attention with Cobalt in the near future. Late as it is in the season, the rush of prospectors and miners up the river continues unabated.

NEW YORK.

After-Election Talk.—Boom in Copper.—Lawson Advertising.—Ray Consolidated.—Nevada Con.—The Curb.

Now that the election is out of the way, the anticipated improvement has started. Men with unemployed capital have no longer an excuse for delay, and to this rather than to any radical change in business conditions is due the fact that it is now possible to obtain a hearing for new ventures. At the same time many of the statements that are published regarding men going back to work in factories, etc., are pure inventions. The industrial depression has been far too deep-seated to be removed in a day or two by the success of a political party. The feeling of confidence that now exists will undoubtedly lead to the extension of old, and the promotion of new, enterprises, and when these plans are executed the demand for materials will bring the factories back to their normal producing basis; but this is not the work of a moment, and the wild stories that are being circulated tend rather to retard than to advance the return of full prosperity. Boston has been having a remarkably busy week in copper stocks; from the low point of 1907, 31 of the more prominent stocks listed on the Stock Exchange there have increased $206,000,000 in value. More recently, however, the Lawson advertising of Utah Copper has adversely affected the general market, as the public now pretty well understands that the object of the advertising is always to sell. The result of the latest effort, so far as can be ascertained, has been the distribution of 25,000 shares of Utah Copper stock from insiders to outsiders. When Lawson took up the Yukon distribution for the Guggenheim, he also got an option from them on stock in the Utah Copper Co., Nevada Consolidated, and Cumberland-Ely, held by the Gugge-heim Exploration Co. and the Guggenheim family, amounting to $1,000,000, but Lawson failed to swing things suffi- ciently to allow him to exercise these options, but prob- ably got another call on Utah Copper. Apart from this, he is supposed to be preparing a large mining flotation, and is probably paving the way by publicly connecting his name with a really successful and well-managed property.

The shares of the Ray Consolidated Copper Co. are now being sold on the New York curb. The mines are in Kel- vin, Arizona, and the ore occurs in large zones in the porphyry, carrying from 2% to 2½% copper, which will be concentrated 15 or 20 to 1. The Ray Consolidated is capital- ized for $3,000,000 first-mortgage 6% bonds, convertible into stock at par until July 1, 1914, and 300,000 shares of stock, par $10. Of the $800,000 shares of stock, 300,000 shares are in escrow for the conversion of the bonds. There remains in the treasury $1,844,000 bonds and 144,400 shares of stocks. Those who can foresee the condition of the Haydon, Stone & Co. until July 1, 1909; this firm will finance the equipment of the mines and erection of a mill if developments continue satisfactory. The company now has approximately $275,000 cash on hand to continue developments. The president of the company is Sherwood Aldrich, of Shove, Aldrich & Co., Colorado Springs. The vice- president is D. C. Jackling, of Salt Lake City, who is vice- president of the Utah Copper Co. The directors are Mon- ald, Jackling, and Shove, J. G. Gordon, of London, Spencer Penrose and C. M. McNell, of the Utah Copper Co., A. Chester Beatty, and S. W. Mudd, who is consulting en- gineer. The executive committee comprises Messrs. Jackling, Beatty, and Mudd.

Advices from Cobalt continue encouraging, and the camp has now looked on with great good cheer. The deal for the silver is very low, but this is not of so much importance, because the metal is produced so cheaply; for example: a rise of 10% in the price would mean an extra profit in some mines of only 12 to 15%, while in other districts such a change would mean the difference between profit and loss. As public attention is directed toward Cobalt, the Gold- field and other Nevada stocks are somewhat neglected, but their turn should be coming short.

In the second annual report of the Nevada Consolidated Copper Co., James Phillips, Jr., the president, says it is confidently expected that construction of the additional unit, the fifth of the series, will raise annual production of blister copper to approximately 70,000,000 lb. From data at hand, it may be accepted with confidence that in Janu- ary, 1909, monthly production will be equivalent to an an- nual production of at least 35,000,000 lb., and that by April next, when additions to the concentrating and smelting plant under way are completed, increased facilities will re- sult in raising annual output to 50,000,000 or 55,000,000 lb. Should Mr. Yeatman's recommendation that still another unit be added meet with the favorable consideration reasonably to be expected of the incoming board, it is within the possibility that this enterprise will take its place as one of the six largest copper-producing com- panies of the world. At the annual meeting the following directors were elected: S. W. Eccles, James Phillips, Jr., W. Hinckle Smith, F. W. Hills, Charles Hayden, C. Hart- man Kuhn, director of the Girard Trust Co. of Philadel- phia; W. B. Thompson, J. K. MacGowan, Williard S. Morse, John N. Steele, and W. E. Bennett. C. Hartman Kuhn suc- ceeds A. Chester Beatty. He is a director of the Girard Trust Co. of Philadelphia, and was added to the board at request of large Philadelphia holders of the stock.

In the meantime an increasing interest is being taken in the stocks on the New York Curb market. A good deal of unfavorable comment has been excited by the manipulation lately of the Orphan stock and of other mining stocks. Owing to the peculiar nature of the Curb it is impossible to regulate all the business done there; the New York Stock Exchange does not permit its members to have dealings with any other organization, and therefore the Curb is not a corporate body at all. The majority of the brokers who conduct business there are willing to abide by such customs as are common at the Curb and of other mining stocks. At the same time no penalty can be inflicted on those who do not conform to the rules. The situation is a delicate one, but a genuine desire exists among the brokers to avoid the abuses that have existed, and to bring to the greatest pos- sible state of efficiency the business of providing a market
that can be used by Stock Exchange houses or others to deal in those shares which for some reason are not suitable for listing on the regular exchange. In pursuance of these ideas, the following notice was issued by the New York Curb Market Agency:

"October 5, 1898. Listing notice. On and after this date all applicants to list stocks will be placed on the blackboard for general inspection and information five days before any sale can be recorded on any of the regular Curb lists. Objections may be filed at this Agency for immediate investigation."

And appended are the forms to be filled in and exhibited. By this means the manipulation of "wild-cats," and subsequent publication of fictitious carb quotations as representing real market values, is largely avoided, and the Curb will be much strengthened in its claims to be considered by the public as the recognized and reputable market for mining stocks.

**MEXICO.**

**Gold at Guanajuato.**—New Developments.—Aerial Trans. — Electric Power.—Zacualpam.—El Oro.—Sinaloa.—Activity in Chihuahua.

Notwithstanding the unprecedented activity in the old camp of Guanajuato, it does not seem to be able to get beyond a weekly production of about $300,000, of which one-third is shipped in the form of ore and concentrate and the remainder as fine bullion from the cyanide mills. It is the continued low and lowering price of silver that has kept down the figures in the value of the production, for the actual number of ounces produced has constantly increased, while the increasing gold production during the last two years is noteworthy. As mentioned in these letters some months ago the higher gold values are found in the system of cross-veins tributary to the Veta Madre; these were first proved of a commercial value in the Carmen mine, and the rich bodies in this small property led to the opening of the Pinguico, which developed into one of the richest bodies on the continent, and led to the deepening of the workings on the adjoining Humboldt, now also approaching the producing stage. Of the others with important gold values are the Naval, with its own little mill; the Tres Coronas, where a mill is in course of construction; and the Guanajuato Gold Mining Co., working the Jesus Maria mine, where a 100-stamp mill was erected to treat the old dump, but untouched because of the excellent bodies of ore in the deposit, of the Panama type. We have also been pushing on the Providencia, near the Pinguico, by the Guanajuato-Providencia M. & D. Co., controlled by Obadiah Sands and associates, of Chicago; and of the San Jose de Gracia by the Mexican Mines Prospect Co., of Mexico City. The success of the aerial tram between the Cata mine and the Buxton mill of the Guanajuato Reduction & Mines Co. has resulted in a similar tram being built from its Tepeyac mine, and it is understood that the gold is now trammed from mine to mill at a cost of 6 centavos per ton, as against a former cost of $1 per ton by burro. For the Sirena mine, of the Guanajuato Consolidated, the pioneer of the modern companies in Guanajuato, two new shafts are being planned. On the Ruby Silver property, adjoining the San Jose de Gracia and recently purchased by John Donaldson, the tunnel is being pushed and good gold ore is being developed; the new work in the San Cavelito is most promising; and the drainage adit of El Cubo is progressing rapidly. The Tajo de Dolores, near the Peregrina and El Cubo, has been taken over on the W. M. Willey option by Catlin & Powell for the Proprietary M. Co. of America, and though but a depth of 300 ft. has been attained, it is stated that ore with a gold value of $2,000,000 has been blocked out and foundations are ready for a 60-stamp mill. The vein, however, has been proved in El Cubo to a depth of 1300 ft. The great call upon the Guanajuato Power & Electric Co., by reason of the developments in Guanajuato, has forced the company to add to its plants at Pundicion and Zacmora, the which when completed, will give the company a capacity of 20,000 horse-power.

Another camp that, like Guanajuato, though much smaller, has shown the result of the stimulus of electricity and cheaper power, is Zacualpam in the State of Mexico. Two years ago the majority of the properties were working in a desultory manner, whereas now, all seems to be in a most prosperous condition. The Seguranza, formerly known as Las Coronas, is in veritable bonanza and a 100-stamp cyanide plant has been ordered. The Orihuela has driven 25 metres in ore and now reports a rich strike. High-grade ore is also being developed in the Carbuncello, the Gerardita, the San Fernando, and the Alacran, this last reporting assays as high as 2000 oz. silver and 30 to 40 oz. gold. The Guadalupe de los Arcos is preparing to re-surface. Cyanide is the password for this camp.

From El Oro nothing new is reported, but the Descubridora is cross-cutting east and west on the 104 ft. level, and it is expected the Descubridora vein will be cut during November. The Campechoa, Triunvirato y Anexas, 10 miles northeast of Leon, in the State of Guanajuato, which has large bodies of low-grade lead and copper ore, has renewed operations and has its new 40-ton mill running at full capacity and is shipping out a carload per week of lead concentrate. The mill will probably be enlarged when prices warrant an increased production. In Sinaloa, the Guadalupe de los Reyes has ordered a steam-electric plant for its mines and reduction works, as has also the Tajo Mines Co., of Rosario, which has placed a $20,000 order with the General Electric Co. The Benito Juarez M. Co., of Salinas, San Luis Potosi has ordered a large mill and cyanide plant. The Certichena, in Tejic, with a good body of 115 gold ore, and will increase its recently constructed 8-stamp mill to 15 stamps.

The Santa Eulalia Exploration Co., in charge of F. Chappellet as assistant manager, and J. H. Gilmore as mine superintendent, is shipping an average of 2800 tons per month to the El Paso smelter, from its Buena Tierra mine. This ore carries 25 oz. silver, 10% lead, 32% iron, 11% lime, 3% manganese, 15% silica. It pays a penalty of 10c. per ton on the silicious ore. The silicious ore, being broken through the rhyolite cap, containing 500 ft. deeper in the limestone. At the 500-ft. station a cross-cut was driven to cut the limestone on its dip, and at this place the orebody was opened. From other lower stations levels were driven to the ore. Steam-power is employed in hoisting and operating an 8-drill Sullivan air-compressor. The Santa Eulalia mines of the American Smelting & Refining Co. are reproducing and developing about 2700 tons per month. The orebody contains 11% lead ore, these shipments being divided between the Chihuahua and El Paso smelters of the company. Its Mina Vieja produces a silicious silver chloride ore, averaging 100 oz. silver per ton; a lime manganese ore, averaging 39 oz. silver, the lime therein running 47%; a sulphide ore, carrying 150 oz. silver per ton and running 50 to 60% calena. The three kinds occur side by side in the same orebody, and are mined and shipped separately. Its Mina Lucio mine produces a low-grade lead ore, which is sent to the Chihuahua plant. A 1000-ft. shaft has been sunk on its Valeradela property, opening bodies of silver-lead ore at the 50 and 750-ft. levels, but no shipments have been made as yet.

An electric plant has been built at the Santo Domingo for the steam hoists. The electric hoists, installed at the Mina Vieja and Valeradela. The steam hoist at the Santo Domingo is still in use. It is probable that the underground workings of the three properties may be connected and the 1000-ft. shaft of the Valeradela be made the main working shaft. An aerial tramway, built by the Trenton Iron Works, two miles long, is being erected from the Mina Vieja to the Santa Eulalia station of the Mineral railroad. W. A. Mitchell is in charge of these operations. —The Chihuahua and Potosi mines are shipping 400 tons of ore per day, 100 tons of which is zinc ore and this is shipped to the zinc works at Gas, Kansas. A new hoisting plant is being installed at the Potosi; it has a double drum and will operate skips to a depth of 1800 ft. This hoist is installed
on the tunnel level, 3600 ft. from the portal, and is operated by compressed air. The Esmeralda and Fortuna are under lease to Howard Anderson, G. B. Jacobs, and others. The former is near the Mina Vieja, has an 18½-ft. shaft and 600 ft. of other work, and has made some shipments of silver-lead ore; the latter is situated in the middle of the Carman group, has considerable old development, and has silicious iron and silver ore. The Veta Grande, in charge of A. H. Donnewald, has sunk a shaft to 40 metres in the porphyry formation, southeast of Santa Eulalia, purely as a matter of exploration. The sinking will continue until the porphyry is passed through and the limestone is encountered. If ore in paying kind and tonnage is found here it will have the effect of starting other work in that vicinity.

**LONDON.**

Lead Mining.—Linares.—Lena Goldfields.—Siberian Companies.—Kyshtim Corporation.—Prospecting for Platinum.

The havoc played on lead mining companies by the depressed market for the metal is well shown in the case of the Linares company, which owns mines in the Linares district of Spain and a smelter at Cordoba. The mines have been worked continuously by the present organization for 26 years, and operations have been directed all the time by John Taylor & Sons. During recent years the management of the mine has been in the hands of Ernest R. Wokes, an engineer known on the American side. The properties are not big producers, but the oresbodies are extensive, and on the small capital outlay have for many years yielded handsome dividends. For instance, on the capital of £45,000 a dividend of £11,550 was paid for the year ending June 30, 1907, being at the rate of 25%. Seeing that the mine has been successful for so many years, we cannot help regretting that the results for the 12 months ended in June last have been seriously affected by the low price of lead, and that the profit has been wiped out altogether. At the beginning of the 12 months the market price for lead was £21 per ton, and at the close only £12½, a drop of no less than 43½%. The expenditure during the year was £98,556, of which £66,501 represented outlay in Spain, £31,103 purchase of smelters' ores, and £2116 expenditure in London. On the other side of the account there is a revenue of £78,758 from sales of lead and an increase in the stock account for unsold products of £15,453. The balance of expenditure is therefore £35,299. The total sales of lead were £110,000, and there was a debit of £17,156 with the Steel & Lead Insurance Company, etc., £71,472. In addition, £7116 was realized by the sale of ore and carbonate locally. The lead sold consisted of 3134 tons of first-class lead, realizing £55,371; 649 tons of rich lead, £14,017; and 292 tons of refined lead, £4706. The prospects of the company for the coming year depend chiefly on the course of the market in metals, but there is also some likelihood of an increased output, owing to another property having been leased and developed to a promising condition.

In a recent issue I gave some particulars of the flotation of the Lena Goldfields Limited, a company formed to acquire extensive tracts of auriferous gravel in the far north-east of Siberia. At the time I cited this flotation in proof of the statement that money was once more becoming available for mining enterprises, I had no idea that I should confess the delay in carrying through the flotation was an equally clear indication that times were bad. It is therefore all the more satisfactory to be able to report now that success has attended the efforts of the directors and that the company will be able to go forward with the scheme. The Lena Goldfields has been floated by the Russian Mining Corporation, which had formed by the latter also an option for 12 months on a property of considerable extent. The prospecting of this property is to be undertaken by a subsidiary syndicate formed for the purpose. F. W. Linek and J. Chisholm are devoting their attention to the work. The corporation will find most of the money required by the syndicate, but other people are also subscribing.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Briquetting iron ore, in order to increase the blast-furnace output, is practised to some extent in England.

The Kalgoorlie water supply contains only 24.24 gr. of solids per gallon, of which 0.17 gr. are solids in suspension.

A steam-shovel on the Panama Canal recently handled 55,419 cu. yd. of soft rock in 25 working days. The machine has a 5-yc. dipper and weighs 95 tons.

Water sterilization by ozone is practised regularly in the Pittsburgh Homeopathic Hospital, where about 100,000 gal. per day are treated, at a cost of 25c. for current.

A coal-handling record was recently made at the new Naragansett Bay Naval Coaling Station, when 2027 tons of coal were taken from the collier New in 7 hours and 10 minutes.

Citizenship of a native-born citizen is proved by his own statement. If naturalization or declaration of intention is the issue, the proper proof is the production of a certified copy of the record.

A brick building, in Chicago, five stories high and estimated to weigh 6000 tons, was recently moved 52 ft. parallel with its width, and then 168 ft. parallel with its length, without mishap or damage to it.

Hot-air heating by utilizing the waste heat of a gas engine is a feature at a Pennsylvania manufacturing plant. Both the exhaust gases and the jacket cooling water are used to heat fresh air, which is cireulated by a fan.

An oval blast-furnace, having an inside minor axis of 10 ft. and a major axis of 18 ft., was recently blown in at an English smelter. The object of the novel shape is to reduce the distance from the tuyeres to the centre of the furnaces, and thus decrease the pressure of the blast.

Concrete of maximum strength and density requires enough rich strong mortar to fill all the voids of the broken stone, gravel, or other aggregate used. If a cheaper concrete is desired, decrease the amount of cement, but use enough of the leaner mortar to fill the voids of the aggregate.

Aluminum is being used in the construction of punching presses, in order to secure high-speed operation. The Standard Machinery Co., of Providence, claims that, because of the lightness of an aluminum plunger and connections in a machine which it has recently built, a speed of 600 strokes per minute has been attained.

Magnesium carbonate is not essential in a rock intended for burning into natural cement, although in the past it has been so considered. On the other hand, silica, alumina, and iron oxide are required to give the hydraulic properties to the resulting product.

The specific gravity of stone or a porous substance is obtained by weighing an absolutely dry sample; weighing the same sample suspended in water, being sure to allow sufficient time for thorough saturation; and then weighing it again in air, removing only the surplus water on the surface. The specific gravity is equal to the dry weight of the stone divided by the difference between the weight of the saturated stone in air and in water.

A thermo-electric couple, for measuring temperatures of molten metals, can be cheaply made by using different forms or grades of graphite for the two elements. It is said that a particularly satisfactory couple is one in which one element is pure carbon or graphite and the other is the same substance combined with 15 to 20% of Bavarian clay. These elements are capable of withstanding extreme heat, and they do not appreciably alloy with most molten metals.

The pressure of wind has been again under investigation at the National Physical Laboratory of England. The experimenters found that for surfaces of 25, 50, and 100 sq. ft., exposed on the top of a tower 50 ft. high, the values of the constant k in the formula \( P = kv^2 \) were identical. Its value, in units of pounds per square foot and miles per hour, was found to be 0.0032. Further experiments show that the resistances of complex structures may be safely predicted from small models.

Painting concrete should not be attempted until it has stood at least one summer. When the surface is thoroughly dry, wash it with an 8% solution of muratic acid, which should afterward be washed off with plenty of clean water. After allowing the concrete to again become absolutely dry, the priming coat may be applied. It should contain so much turpentine that it is almost flat. The oil in the seeresive coats should be increased, and each one allowed time to dry thoroughly before the next is applied.

A producer gas dredge is excavating a canal in Iowa with a low coal consumption. The machine is of the bucket-ladder type, and delivers the material to the spoil bank on each side of the canal by two 80-ft. pan conveyors. The elevator is equipped with 66 buckets of 9 cu. ft. capacity, dumping at the rate of 40 buckets per minute, which gives a capacity of 19,000 cu. yd. per 24-hr. day. The dredge is operated by a 150-hp. producer gas engine, using peat-ash anthracite coal in the producer. The engine also drives a 35-kw. generator, which supplies power for motors operating the pan conveyor, and current for lighting the dredge. The coal consumption is about 2 tons per 24-hr. day, of which 20 hr., are actual mining time. This type of plant was used because of the difficulty of transporting fuel across the adjacent bottom lands.
Discussion.

Government Assistance.

The Editor:

Sir—On visiting the underground workings of the Comstock Lode lately, I was impressed with the financial difficulties under which the Comstock Pumping Association is laboring in draining and ventilating the mines. The work of keeping in repair the Sutro Tunnel and its laterals is handicapped at every point for the want of adequate funds. Instead of being able thoroughly to renew and repair the timbering, the management can only take the worst places in hand. The total expenditure, working in this piecemeal way, is much greater than would be the case if funds were available to carry on the work in a thorough manner.

It is repugnant to Americans to have government interference in such work, but it seems to me that if ever government assistance to mining was warranted it is here. The companies themselves cannot efficiently do what should be done. None of them has the funds to do so, most of them have not shareholders who would submit to be assessed, and those which could raise the money would not be justified in undertaking by themselves what would accrete to the benefit of all. Even supposing that all the companies were in a position to pay, it would be impossible to arrive at an agreement as to the proportion of the expenditure to be borne by each.

The State of Nevada should establish a board to take a hand in the removal of the water at present being pumped, and the further quantities which will be encountered in the deepening of, say, two shafts. This board should be authorized to make a bond issue, the principal and interest of which would be guaranteed by the State of Nevada. The tax-payers should have no objection to the State becoming responsible for such a bond issue; the members of the farming community should be willing, because they benefited for many years from the money disbursed at Virginia City; the miners should be willing to help their brothers who are at present 'up against it.' The board should have the right to levy a tribute on all ore taken out from any of the mines benefited by the drainage system. The amount of the bond issue and the tribute to be levied should be determined after investigation by some competent authority. As to the composition of the board, it seems to me that public-spirited men might be found to take the appointments at merely nominal fees.

I do not know if what I propose is practicable under the conditions that prevail here, and quite appreciate that if the thing were taken in hand there would be many difficulties to overcome; but I am certain that if the same conditions existed in the Transvaal or Australia, something of the sort would be done.

Because a mine has been a large producer, it is of course not certain that it will be again, but in this case, as the geological conditions remain unchanged at the deepest levels, it is reasonable to suppose that valuable deposits will again be found. Indeed, from a cursory inspection of the underground maps, I think it very likely that, if the management had the drainage problems off their hands, they would discover bodies of pay-ore without sinking farther.

Francis Drake.

Copper Averages at the Nevada Consolidated.

The Editor:

Sir—Referring to the article by M. L. Requa, 'Experimental Mill of the Nevada Consolidated Copper Co.,' in your issue of July 18, the method given for calculating the approximate extractions is worth discussing. Mr. Requa's carefully drawn up figures yield much information, but the method of arriving at the approximate extractions is surely not quite correct. Among the details are the following headings: 'dry crude ore in pounds,' 'percentage of crude copper,' 'percentage of copper in the tailing,' 'percentage of approximate extraction,' and so forth; the figures under each heading are added up; and the sum is then divided by the number of 'lots' to get the average in the case of each heading. The question is, should the percentages of extraction be so divided? On one occasion I was checking some figures of 'heads' and 'tailings' from the returns of a gold-milling plant, and the same thing was done to obtain the theoretical extraction; but another method gave a difference of 2½ per cent.

In the case under discussion the different 'lots' vary in weight. Should not one of the following methods be adopted?

No. 1. Multiply the 'approximate extraction percentage' for each lot by the respective tonnage, add the products, and divide by the sum of the tonnages. By this method the following differences are obtained in the case referred to:

<table>
<thead>
<tr>
<th>Method</th>
<th>Requa</th>
<th>Parsons</th>
</tr>
</thead>
<tbody>
<tr>
<td>200-ft. level tests</td>
<td>73.59</td>
<td>73.92</td>
</tr>
<tr>
<td>300-ft. level tests</td>
<td>75.58</td>
<td>75.58</td>
</tr>
<tr>
<td>500-ft. level tests</td>
<td>75.51</td>
<td>74.92</td>
</tr>
</tbody>
</table>

No. 2. Obtain the average of the whole, first, by multiplying the tonnage of each lot by the assay percentage of that lot, add the tonnages together, and then the multiplied results obtained; divide the total tonnages into the sum of the multiplied results; then in the same way multiply the tonnage of each lot by the copper percentage in the tailing of that lot, and from the two figures obtained calculate the average extraction. The following are the comparative results:

<table>
<thead>
<tr>
<th>Method</th>
<th>Requa</th>
<th>Parsons</th>
</tr>
</thead>
<tbody>
<tr>
<td>200-ft. level tests only</td>
<td>73.59</td>
<td>73.58</td>
</tr>
</tbody>
</table>

The differences are insignificant, but the question is, which is the correct method? Mr. Requa has taken no account of the varying tonnages of the lots; he simply divides the sum of the extractions by the total number of the lots, and though it makes little difference in this case, in others it might amount to
MINING AND SCIENTIFIC PRESS

November 21, 1908.

Cyril E. Parsons.

London, October 12.

[We submitted Mr. Parsons' letter to Mr. Requa, and the reply of the latter is given herewith. It explains the point raised.—Editor.]

The Editor:

Sir—There can be no question regarding the correctness of Mr. Parsons' method of arriving at the correct value of ore. The use of foot-ounces or foot-dollars is, of course, the only way to get the actual value of developed ore. This method gives the proper value to each block of ground in estimating tonnage. In the ease of the Ruth mine, however, giving to the various lots the value dependent upon their weights would have produced an erroneous result. The lots did not represent any specific tonnage. On the contrary, in order to arrive at a fair and accurate average, the weight of the lots necessarily must be neglected in the computation. For instance, take the lot of September 24, 140,000 lb., assaying 2.8% copper. This lot was far in excess of any of the others, but it did not represent any such excessive tonnage in the mine as would be indicated by the weight of that particular lot. The method of sampling was to take as nearly as practical an equal number of pounds each day from a given number of linear feet. It so happens that the character of the orebody of the Ruth mine is such that a variation of several thousand pounds in a lot would in all probability make no difference in the final result, but giving a value to the weight of the lots in proportion to the total weight might produce an erroneous result. The Ruth orebody is a very different problem from the sampling of an ordinary vein of a few feet in width that swells in and out, so that it is necessary to use the foot-dollar or foot-ounce method in order to arrive at the gross value of the tonnage developed. The Ruth orebody is a mineralized porphyry roughly wedge-shaped with the small end up; it has an extreme area of something like 1000 ft. long and 350 to 400 ft. wide, with ore still in the north faces of the cross-cuts.

In my opinion, the only way to arrive at a fairly accurate value of this ore is to take the value of a great many samples, neglecting the tonnage represented by any one particular sample, then carefully calculating the contents of the area of ore exposed, and applying to it the average value as determined by these samples. It would be impossible to take any one sample or any dozen samples and specifically say that they represented so many tons of ore of this grade. The orebody as a whole is extremely uniform over large areas and hundreds of samples, but there are some erratic occurrences of enriched and leached zones over widths of 10, 15, or 20 ft. or more that if segregated and applied to an individual area might produce results not at all in keeping with the average of the orebody as it will be mined. For this reason no value was given to the percentage of tonnage represented by any one lot in making the mill-tests.

M. L. Requa.

San Francisco, November 11.

Chlorination in California.

The Editor:

Sir—I have read with interest and carefully digested the article on 'Chlorination in California.' by Wilton E. Darrow; but in my experience a mechanical roasting furnace does not give the dead roast requisite for the highest efficiency of chlorination.

It is true that hand-rabbed reverberatories will leave unoxidized lumps and fused sinters, unless most skilfully and conscientiously attended. It is also true that, in general, the addition of salt to the charge before, or at the time of, dumping to the hearth, will clinker the sulphides, and volatilize the gold; and, if the concentrate contains tellurides, as much as 40% of the gold will be carried away, and be partly condensed when touching any cold surface. This was proved, with great personal loss, by C. H. Aaron, when he was operating a chlorination plant at Melrose, in the early eighties, until he found a yellow sublimate of pure gold on the outside of the brick walls of the furnace, above the rabbling-doors.
He was at the time working concentrate from the Marlie Mine of Nevada county, which contained appreciable amounts of both tellurium and selenium, in the form of narygite, locally called galena or "blue mineral." This concentrate also carried 31.5% of copper, and was high in silver, with a total value of $384 per ton. Other shipments of concentrate from the same mine were tried at the different chlo- 
ization works, but none of them could save more than 80% of the value, though allowing 90% on the 
assays made at the plants.

Then mechanical furnaces of the Bruckner and White-Howell types were tried, with equally poor results. Finally we found a plant where the assays of both the mine and plant samples exactly tallied, 
and a trial was made here, at which I assisted, on about 50 tons of the concentrate. The results were 
very good: 98% of the silver, 99% of the gold, and 
sufficient cement copper for the actual working 
charges. I have not heard of the furnace for 
years, and whether it was held under patent right 
or not I do not know. It was called the Crosby furnace, 
and allowed perfect control of the final desul-
phurization.

Briefly stated, it consisted of a revolving cylinder, 
open at both ends, and with lifting divisors to carry 
the sulphides up, and drop them through the flame.

Sketch of the Crosby Furnace.

It was set at a slight angle, the concentrate was fed 
continuously at the upper throat and automatically 
dropped on a stationary hearth, 10 ft. square, fed by a 
wood fire at one side, and with a stirring-door in front, and a bottom discharge. When sufficient 
partly oxidized concentrate had accumulated on this 
hearth, it was hand-rabbled until a sample showed 
only the faintest trace of sulphate by the addition of 
barium chloride. Then a charge of less than 2% of 
salt was added, quickly stirred with the roast, and 
immediately all was discharged and spread out to cool.

As Von Bibber writes, "The first blow generally 
decides the battle," and the subsequent chlorination was so efficient that we were able to get the high 
extration stated above. The leach carried nearly all the 
copper, and after the precipitation of the gold by 
ferrous sulphate, the resultant liquor was run 
through sluices in which had been placed wrought-
iron scrap, and the copper was saved in the form of 
cement. The leached roast still carried the silver, 
and this was extracted in other tanks, by hydrosul-
phite of soda.

From my experience on this complex and high-
grade concentrate, as well as later practice with dif-
ferent types of mechanical furnaces, I would strongly 
advise the finishing by hand-rabbling, no salt to be 
added till just before discharging, and then in the 
smallest amount to neutralize the silver, zinc, lead, 
and copper present. Eliminate all the sulphate, and 
add no sulphuric acid, as the salt will prevent any 
undue consumption of chlorine gas, and, when the 
salt is added in this way, it will not volatilize any 
appreciable amount of gold, nor imprison it in a non-
porous slag. Prepare your concentrate in this way 
and the subsequent high extraction of the gold will 
be easy.

San Francisco, November 5.

W. J. Adams.

In testing for tungsten, unless the suspected min-
eral be present in quantity, the material should be 
concentrated by panning or careful selection. To 
test scheelite, place a portion of the powdered min-
eral the size of a pea in a test-tube or cup, and 
cover with a teaspoonful of hydrochloric acid. Upon 
boiling a few minutes or, if not heated, allowing to 
stand a considerable time, tungsten trioxide, WO₃, a 
bright yellow powder, is formed. Upon dropping 
metallic tin or zinc into the cup the yellow powder 
is reduced to a lower oxide, which is of a beautiful 
blue color, and later to still lower oxides of other 
colors. With zinc the solution first turns blue, then 
wine colored, and later brown. When the reduction 
takes place quickly the blue color of the solution 
may not be seen at all, the first color to appear being 
a reddish lilac, quickly turning brown. With tin, it 
turns successively blue, lilac, wine colored, and more 
slowly to brown. The wine color may last for hours. 
Tinfoil, which is ordinarily composed largely of tin, 
with varying amounts of lead, may be used. In the 
reduction with tin the solution nearest the tin will 
often have a lilac or wine color, while a short dis-
tance away the solution will be a fine blue. With 
either zinc or tin the powdered mineral itself will be 
colored blue, even though the solution may be of a 
different color. When treated with acid several min-
utes should be allowed to elapse before introducing 
zinc or tin; otherwise the yellow oxide may not be 
formed in sufficient amount to give a good reaction, 
and neither the blue nor the pink color will be seen, 
but the solution will be a yellowish brown. How-
ever, a blue sediment will form in the bottom of the 
vessel. If one part of hydrochloric acid diluted 
with two parts of water be used, tin gives to the solu-
tion a blue color which lasts a considerable time. 
Sulphuric acid diluted with two or three parts of 
water may be used instead of hydrochloric, and 
seems to be the more active of the two in changing 
scheelite to tungsten trioxide. It is slower than 
hydrochloric acid in reducing the yellow oxide to the 
blue oxide upon the addition of zinc, and needs 
more heating, but gives the same blue color, which 
is more lasting and may still show after standing 
24 hours. With tin, sulphuric acid acts still more 
slowly, and requires considerable heating, but gives 
the same lasting blue color. Nitric acid gives the 
yellow tungsten trioxide, but will not give the fur-
ther reactions.
THE ESTIMATION OF SULPHO AND FERROCYANIDES IN CYANIDE SOLUTIONS CONTAINING COPPER.

By Leonard M. Green.

*In the majority of working solutions obtained in the cyanide treatment of silver ores, and also in many solutions obtained in the treatment of gold ores, copper is present. This element, even in small amount, enormously complicates the determination of ferro and sulphocyanides, and usually prohibits their determination by ordinary methods. This is due to the fact that both cupric and cuprous double cyanides exercise a reducing action on permanganate in acid solution, and that they precipitate both ferro and sulphocyanides. If, therefore, acidified permanganate be titrated with a solution containing sulpho and ferrocyanides in presence of cupric and cuprous double cyanides, the reducing power is equivalent to the sulpho and ferrocyanides plus the reducing power due to the copper compounds, and, in order to find the reducing power due to the two former constituents, that due to the latter must also be determined. Again, in the separation of the ferrocyanide from the sulphocyanide by precipitation as prussian blue, some sulphocyanide may be precipitated as cuprous sulphocyanide along with the ferrocyanide precipitate, and thus escape estimation as sulphocyanide.

Before suggesting tests for the determination of the constituents it will be of interest to describe some of the reactions which may take place during the testing and treatment of such solutions.

The cyanide in combination with copper in a cyanide solution is not indicated by the ordinary silver nitrate and iodide test, but with certain precautions it may be estimated by titration with mercuric chloride. If the solution be directly titrated with mercuric chloride no definite end-point is obtained, for the indication will be affected by the quantity of protective alkali and of certain other salts present.

If, however, the protective alkali be neutralized and an excess of ferrocyanide be added, together with a few c.c. of potassium mercuric iodide indicator (HgI₂·2KI), a perfectly definite end-point is obtained, corresponding to the alkaline cyanide plus the zine double cyanide plus the cuprous double cyanide plus three-quarters of the cupric double cyanide. The mercuric chloride first attacks the alkaline cyanide and then the zine double cyanide (if present), forming mercuric cyanide, zinc ferrocyanide, and potassium chloride.

2KCy + HgCl₂ = 2KCl + HgCy₂,
6K₂ZnCy₄ + 4K₂FeCy₄ + 12HgCl₂ = 12HgCy₂ + K₂FeCy₄·3Zn₆FeCy₄ + 24KCl.

It then attacks the cupric double cyanide, neutralizing ¾ of the cyanide which it contains.

12K₂CuCy₄ + 4K₂FeCy₄ + 18HgCl₂ = 18HgCy₂ + K₂FeCy₄·3Cu₆FeCy₄ + 36KCl + 6Cy₂.

The cyanogen set free in this reaction probably either decomposes or passes off as gas, but in the presence of an excess of ferrocyanide a small amount may perhaps form ferrocyanide, which does not interfere with the other reactions. Finally it attacks the cuprous double cyanide, combining with the whole of the cyanogen it contains.

12KCuCy₂ + 4K₂FeCy₄ + 12HgCl₂ = 12HgCy₂ + K₂FeCy₄·3Cu₆FeCy₄ + 24KCl.

The next drop of mercuric chloride solution attacks the indicator, forming a red precipitate of mercuric iodide.

HgI₂ + 2KI + HgCl₂ = 2HgI₂ + 2KCl.

This test, therefore, indicates the alkaline cyanide plus the zine double cyanide plus the cuprous double cyanide plus ¾ of the cupric double cyanide in terms of K₂Cy, and starting from this point it is possible to devise tests to differentiate the various salts included in this total. Instead of neutralizing the protective alkali, practically the same indication is obtained by adding a little bicharbonate of soda, for although alkaline hydrates influence the titration, carbonates and bicarbonates barely affect the result. It was formerly considered that this test indicated the whole of the cyanide combined with the copper, but this would involve the formation of cupric ferrocyanide, and I have noticed that even in solutions containing large amounts of cupric double cyanides there is barely a trace of pink color in the precipitate formed, which remains almost milk-white throughout the test, showing that, even from the cupric double salt, cuprous ferrocyanide is precipitated, and, therefore, that the hypothetical presence of cupric ferrocyanide is extremely improbable.

If the test be performed in the absence of ferrocyanide, the other conditions remaining the same, provided that the indicator be present in sufficient amount to form a double iodide of mercury and copper with the cuprous copper in the solution, then the red end-point occurs when the alkaline cyanide plus the zine double cyanide plus ¾ the cyanide occurring as cupric double cyanide plus the cuprous double cyanide have been neutralized, the remaining ¾ of the cyanide being left unattacked as Cu₂Cy₂. In this case the red mercuric iodide precipitate occurs in the midst of a yellow precipitate of a double iodide of mercury and copper, which is formed when the cuprous copper is turned out of its combination with cyanide. If when the red precipitate is just formed ferrocyanide be added to the solution, the precipitate becomes white owing to the reaction of the ferrocyanide with the mercuric cuprous iodide.

6(HgI₂·2CuI) + 4K₂FeCy₄ = K₂FeCy₄·3Cu₆FeCy₄ + 6(HgI₂·2KI),

and at the same time the cupric cyanide is rendered amenable to the attack of mercuric chloride, so that an additional amount equal to ½ the Cu₂Cy₂ or ¾ of the original K₂CuCy₂ may be added before the red precipitate of mercuric iodide is again produced.

12CuCy₂ + 4K₂FeCy₄ + 6HgCl₂ = K₂FeCy₄·3Cu₆FeCy₄ + 6HgCy₂ + 12KCl + 6Cy₂.

In the absence of ferrocyanide, a copper cyanide solution containing sulphocyanide, and having had its protective alkali neutralized, when titrated with mercuric chloride gives a light yellow precipitate.
when the alkaline cyanide plus the zinc double cyanide plus \( \frac{1}{2} \) the cupric double cyanide has been neutralized with mercuric chloride. The precipitate appears to be a double sulphyd cyanide of mercury and cuprous copper. It does not form in the presence of ferrocyanide unless sufficient zinc be present to combine with the whole of the ferrocyanide. Instead of neutralizing the protective alkali it may be precipitated by the addition of sulphate of zinc, the excess of zinc sulphate not interfering with the reaction. The yellow precipitate when occurring in the presence of a white precipitate is best observed against a dead white background.

When a cyanide solution containing both cupric and cuprous double cyanides is acidified, the cuprous double cyanide forms hydrocyanic acid and cuprous cyanide, whereas the cupric double cyanide forms hydrocyanic acid and cupric cyanide, or if strongly acidified, hydrocyanic acid, cuprous cyanide and cyanogen. Titration of the acidified solution with permanganate is very tedious and difficult, for the cuprous cyanide is but slowly acted on. If, however, the solution has been strongly acidified, the redox reaction of the solution being proportioned to the cuprous copper plus the cupric copper:

\[
2\text{KCuCy}_2 + 3\text{H}_2\text{SO}_4 + \text{O} = 2\text{K}_2\text{SO}_4 + 2\text{CuSO}_4 + 4\text{H Cy} + \text{H}_2\text{O}
\]

\[
2\text{K}_2\text{CuCy}_4 + 4\text{H}_2\text{SO}_4 + \text{O} = 2\text{K}_2\text{SO}_4 + 2\text{CuSO}_4 + 6\text{H Cy} + \text{Cu}_2 + 2\text{H}_2\text{O}.
\]

If the permanganate be very weakly acidified it is possible to obtain a reducing power equal to the cuprous copper plus twice the cupric copper, owing to the fact that the cyanogen set free from the cuprous compound, instead of spontaneously decomposing, is oxidized by the permanganate:

\[
2\text{K}_2\text{CuCy}_4 + 4\text{H}_2\text{SO}_4 + \text{O}_2 = 2\text{K}_2\text{SO}_4 + 2\text{CuSO}_4 + 6\text{H Cy} + 2\text{H}_2\text{CyO}.
\]

In general, however, with weakly acidified permanganate some of the cyanogen set free spontaneously decomposes, so that the result obtained is somewhat less than that indicated above. With a strongly acidified permanganate, 1 gm. copper oxidizes 0.50 gm. permanganate (K,MnO). When the solution contains sulphonycyanide, acidification causes the precipitation of cuprous sulphyd cyanide, both from the cuprous and from the cupric double cyanide:

\[
2\text{KCuCy}_2 + 2\text{H}_2\text{SO}_4 + 2\text{KSCy} = 2\text{CuScy} + 2\text{K}_2\text{SO}_4 + 4\text{H Cy}
\]

\[
2\text{K}_2\text{CuCy}_4 + 3\text{H}_2\text{SO}_4 + 2\text{KSCy} = 2\text{CuScy} + 3\text{K}_2\text{SO}_4 + 6\text{H Cy} + \text{Cy}_2.
\]

One gm. of copper precipitates 1.528 gm. KSCy. On titrating the acidified solution with permanganate, the whole of the copper and of the sulphyd cyanide are oxidized:

\[
2\text{CuScy} + \text{O}_2 + \text{H}_2\text{O} = 2\text{Cu}_2\text{O} + 2\text{H Cy}.
\]

There is no difficulty in the titration, for the cuprous sulphyd cyanide is readily acted on by the permanganate. Practically the same result is obtained whether the solution be strongly or weakly acidified. If strongly acidified permanganate is titrated with the solution, practically the same result is again obtained. If the permanganate be weakly acidified, some of the cyanogen set free in forming CuSCy from the cupric double cyanide is oxidized by the permanganate, and the reducing power of the solution is consequently somewhat higher.

When a solution containing ferrocyanide is acidified, it might have been expected that both cupric and cuprous ferrocyanide would be precipitated. This, however, is not the case, the whole of the copper coming down as cuprous ferrocyanide.

\[
12\text{KCuCy}_2 + 4\text{K}_2\text{FeCy}_4 + 12\text{H}_2\text{SO}_4 = 12\text{K}_2\text{SO}_4 + 2\text{H}_2\text{Cy} + \text{K}_2\text{FeCy}_4 + 3\text{Cu}_2\text{FeCy}_4
\]

\[
12\text{K}_2\text{CuCy}_4 + 4\text{K}_2\text{FeCy}_4 + 18\text{H}_2\text{SO}_4 = 18\text{K}_2\text{SO}_4 + 3\text{H}_2\text{Cy} + \text{K}_2\text{FeCy}_4 + 3\text{Cu}_2\text{FeCy}_4 + 6\text{Cy}_2.
\]

Sometimes there is a slight oxidation of the cuprous ferrocyanide with the production of a trifling amount of cupric ferrocyanide. If the acidified solution be titrated with permanganate, a reducing power equivalent to the whole of the copper plus the ferrocyanide is obtained. The result is practically the same whether the solution is strongly or weakly acidified:

\[
\text{K}_2\text{FeCy}_4 + 3\text{Cu}_2\text{FeCy}_4 + 4\text{O}_2 + 14\text{H}_2\text{SO}_4 = 12\text{Cu}_2\text{SO}_4 + 2\text{H}_2\text{FeCy}_4 + 8\text{H}_2\text{O} + 2\text{K}_2\text{SO}_4.
\]

Sometimes there is a slight oxidation of the cuprous ferrocyanide with the production of a trifling amount of cupric ferrocyanide. If the acidified solution be titrated with permanganate, a reducing power equivalent to the whole of the copper plus the ferrocyanide is obtained. The result is practically the same whether the solution be strongly or weakly acidified:

\[
\text{K}_2\text{FeCy}_4 + 3\text{Cu}_2\text{FeCy}_4 + 4\text{O}_2 + 14\text{H}_2\text{SO}_4 = 12\text{Cu}_2\text{SO}_4 + 2\text{H}_2\text{FeCy}_4 + 8\text{H}_2\text{O} + 2\text{K}_2\text{SO}_4.
\]

If strongly acidified permanganate be titrated with the solution, the same reducing power is shown, but if the permanganate be only weakly acidified, the reducing power is somewhat higher owing to the oxidation of cyanogen. In the titration of the acidified solution with permanganate, the precipitate which was originally white or nearly white turns first to a dark purplish black, and then, on continuing the titration, becomes dark brown and finally a light yellowish brown, in which latter solution the first red tinge of the permanganate has to be noted. When permanganate is titrated with solution, after the removal of the red color of the permanganate, the solution remains of a yellowish brown or yellowish green color.

When both ferrocyanide and sulphyd cyanide are present in the solution which is acidified, the copper combines with the ferrocyanide in preference to the sulphyd cyanide, and if sufficient ferrocyanide be present no sulphonycyanide is precipitated. The reducing power of the solution is equivalent to the total copper plus the sulphonycyanide plus the ferrocyanide.

The following tests are based on the foregoing reactions, and have been elaborated from a study of the working cyanide solutions from several cyanide plants in Mexico treating gold and silver ores, which also contained more or less copper. The following solutions are required:
Standard solutions:
Silver nitrate, 13.05 gm. (AgNO₃) in 1 litre of water.
Mercerite chloride, 20.846 gm. HgCl₂ in 1 litre.
N/10 permanganate, 3.18 gm. K₂MnO₄ in 1 litre.

Approximate solutions:
Sulphocyanide to approximately equal permanganate.
Zinc sulphate solution. 10% ZnSO₄, 7H₂O.
N/10 ferrocyane, 42.2 gm. K₃Fe(CN)₆·3H₂O per litre.

(1) Take 10 e.c. of solution. Add a small crystal of potassium iodide and a little soda solution and titrate with silver nitrate till there is a permanent yellowish cloudiness. Result = 'a' e.c.

This result represents potassium cyanide equivalent to the alkaline cyanide plus the zinc potassium cyanide.

(2) Dissolve a small crystal of potassium iodide in a few e.c. of water and add 5 e.c. ferrocyane solution and a pinch of bicarbonate of soda. To this add mercerite chloride solution drop by drop, till there is just a permanent red precipitate. A convenient amount of iodide is enough to combine with from 1 to 2 e.c. of the mercerite chloride solution. To this add 10 e.c. of the cyanide solution to be tested, and then titrate with mercerite chloride until there is a permanent reddish coloration. Result = 'b' e.c.

This result represents potassium cyanide equivalent to the alkaline cyanide plus the zinc potassium cyanide plus the cuprous potassium cyanide plus 3/4 of the cupric potassium cyanide.

If silver be present there will be a lemon yellow coloration before the end-point, which will then appear of a deep orange color. If silver be present in large amount, the amount of cyanide combined with it must be calculated and deducted from the amount shown in the test above to get the true value of 'b'.

(3) Take 10 e.c. of the cyanide solution, add 20 e.c. sulphydric cyanide solution and 5 e.c. zinc sulphate solution. Titrate with mercuric chloride solution till the precipitate remains of a permanent faint yellow tinge. This is best seen by placing the vessel in which the titration is performed on a sheet of clean white paper. Result = 'c' e.c.

This result represents potassium cyanide equivalent to the alkaline cyanide plus the zinc potassium cyanide plus 1/2 of the cupric potassium cyanide.

(4) Acidify about 10 e.c. of water very strongly with sulphuric acid and cool. Then add 10 e.c. permanganate and titrate this with the cyanide solution. In the presence of ferro and sulphydric cyanides, at the end of the reaction when the pink color of the permanganate is removed the solution will remain of a brownish or greenish yellow color. Calculate the reducing power of 10 e.c. of solution in terms of permanganate. Let 10 e.c. of solution reduced = 'd' e.c. permanganate.

This result gives the amount of permanganate reduced by the sulphydric cyanide plus the ferrocyane plus the whole of the copper.

Sulphides and organic matter, should they be present, must either be removed previous to testing, or estimated and allowed for.

(5) To 25 e.c. of solution add 5 e.c. ferrocyane solution and acidify with H₂SO₄; then add 5 e.c. zinc sulphate solution and make up to 50 e.c. Shake up and filter through a dry filter. Titrate 20 e.c. of the filtrate with permanganate. Result = 'e' e.c.

This result gives the amount of permanganate reduced by the sulphydric cyanide alone. Then Alkaline plus zinc double cyanide—

Estimated as K₂Cy = —— %

Cuprie double cyanide—

Estimated as K₂Cy = —— %

Cuprous double cyanide—

Estimated as K₂ = —— %

Potassium sulphocyanide—

(K₂CyS) = e × 0.0162%

Potassium ferrocyanide—

K₃Fe(CN)₆·3H₂O = (d — — e) × 0.422%

Total copper = —— %

In the tests given the results have all been determined on 10 e.c. of solution. If convenient, a larger amount may, of course, be tested, the quantities of reagents added being increased and the factors for the results being decreased proportionally.

Weights of steel bridges may be estimated by the following formulas. The approximate weights of bridges of different types (up to 550 ft. spans) have been obtained from actual construction, and if there is any criticism to be made against them, it is that they are too close an approximation. The term 'hot metal bridge' applies to a structure having a solid buckle-plate floor system and sides sufficient to provide protection for river and other travel underneath during the transit of hot metal from furnaces to the mills, as practiced at Pittsburgh.

1. Ordinary pin-connected through truss, open-floor system, single track, W = 7.5L² + 500L.
2. Do., double track, W = 12L² + 1000L.
3. Double track, through truss, pin-connected, solid-floor system of furnace sand; hot metal bridge, W = 16L² + 280L.
4. Ordinary floor plate girders, single track, open floor, W = 10L² + 350L.
5. Do., hot metal, W = 12L² + 1500L.

Where W = total weight of steel work in pounds and L = extreme length in feet.

The design is based on a live load similar to Cooper's class E50, but with particularly heavy loads on cars suitable for hauling molten metal. —Proceedings of the Engineers' Society of Western Pennsylvania.
SNOWSTORM COPPER DEPOSIT.

*What is commonly referred to as the copper belt of the Coeur d'Alene district, Idaho, is an area not susceptible to precise delimitation, but which lies east of a meridian through Stevens peak and south of Canyon creek, thus being in the southeast corner of the district. How far south it extends is not known. Within this belt are one productive mine, the Snowstorm, and several prospects. In 1904 the Snowstorm had produced about $60,000. In 1906 the production had risen to 82,679 tons for the year, with a gross value of $1,069,324. The improvements in 1905 and 1906 cost $152,350, and the net profits amounted to $150,000.

The deposit of the Snowstorm mine consists of disseminations of bornite, chalcoite, and chalcopyrite in certain beds of the Revett quartzite. The greater part of the sulphides, however, has been oxidized to cuprite and malachite. The various prospects are on metasomatic fissure veins carrying chalcopyrite, chalcoite, or bornite, with quartz, dolomite, or siderite.

The Snowstorm mine, which has lately come into prominence as the only producer of copper ore in the district, is situated near the head of Daisy gulch, 3½ miles east-northeast from Mullan, the principal adit being at an elevation of approximately 5100 ft. Work on this property began in November, 1903, and at the time of visit the mine had been well opened for stoping and was connected with the railway at the mouth of the gulch by a Riblet aerial tramway. A leaching-mill was also in process of construction at the lower terminus of the tramway. The total production of the mine in August, 1904, amounted to about $60,000, practically all from development work. The mine, except the lower tunnel, which is not yet producing ore, was then worked by lessees, who had constructed the tramway.

The leaching-mill has since been successfully operated, the process being reported as follows:"

"An extraction of about 97% is said to be obtained at the Snowstorm mill at Larson, Idaho, where a copper carbonate ore is being treated. After crushing, the ore is run into agitators, where it is mixed with a 10% solution of sulphuric acid and a solution of chloride of lime. Thus a solution of copper sulphate is formed, while the silver remains as a precipitate of chloride. From these agitators, which are three in number, the copper sulphate solution goes through a series of six settling vats. From the solution, the copper is precipitated with scrap-iron, and the residues, containing the silver chloride, are treated with sodium thiosulphate. The solution of silver thiosulphate thus obtained is passed through settling-vats, and the silver is precipitated from the clear solution by sodium sulphide, the precipitate being filtered and shipped for refinement. The ore runs from 2½ to 3½% copper and about 7 oz. silver."

The mine is opened by three tunnels, which cross-cut northeast to the ore. The middle or No. 2 tunnel is the most important, and is the one from which ore is being shipped. No. 3 tunnel has reached the lode, which has been explored for about 400 ft. on this level. No workable bodies of ore had been found in this tunnel, however, at the time of visit.

The lode is a zone of impregnation which embraces one or more beds of the Revett quartzite, and conforms to the bedding of the rocks in which it lies. It strikes N.60°W. and dips to the southwest at an angle of 65°. In some places the zone of mineralization is 40 ft. wide. There is apparently no lithological difference between the quartzite that carries the ore and that which forms the country rock. Neither is there any pronounced or persistent fissuring along the lode, such as might be supposed to have determined ore deposition in its vicinity. The ore occurs impregnating the apparently un fissured quartzite, and along joints and small irregular fractures. Microscopic study shows, however, that the quartzite has been crushed and that it is traversed by a network of microscopic fractures. These capillary openings, invisible to the unaided eye, gave access to the ore-bearing solutions. The deposit as a rule has no definite walls, although the ore is locally limited by bedding planes in the quartzite.

All the upper workings are in the Revett quartzite. No. 3 tunnel, however, enters in the slaty rocks of the St. Regis formation. About 100 ft. south of the lode this tunnel passes through a well-defined fault-breccia into the Revett quartzite. As the St. Regis is stratigraphically above the Revett, the fault is clearly a reverse or thrust fault. The throw is unknown, but can not be less than 700 ft. The fault must cut the ore-bearing zone only a short distance below the tunnel. The fault shows no mineralization and contains about 10 ft. of clay gouge. These facts would ordinarily be taken to indicate that the fault is later than the ore. In this district, however, such

†MINING AND SCIENTIFIC PRESS, June 22, 1907, p. 782.
a conclusion can not safely be drawn, and the relative age of fault and ore must remain for the present undetermined. In any event it is unlikely that the present orebody can be followed for much more than 100 ft. below No. 3 tunnel.

In No. 2 tunnel the ore-shoot is at least 500 ft. long, although the ore in the faces of the drift at the time of visit was of low grade. In No. 3 tunnel, as already mentioned, no orebodies of commercial importance have yet been found.

In its unoxidized form the best ore consists of quartzite so crowded with little specks and small irregular bunches of bornite, chalcocite, and chalcopyrite as to be dark gray or nearly black. The microscope shows that the ore-minerals to some extent fill irregular microscopic fissures, but that for the most part they have replaced the interstitial sericite and siderite of the country quartzite.

Comparatively little of the ore, however, remains in its sulphide condition. Most of it has been oxidized to cuprite and malachite. There is no well-defined zone of oxidation, most of the sulphide ore occurring in No. 2 tunnel, and some carbonate in No. 3 tunnel. The latter tunnel is very wet, a large flow of water having been encountered as soon as the quartzite was cut. This water, however, evidently comes from the surfaces of the neighboring ridges and is oxidizing in its character. It is held in all the fissures in the brittle quartzite and is dammed on the southwest by the clay gouge of the fault.

The average tenor of the ore, as shipped in 1904, was 4% copper, with about 6 oz. silver and 0.1 oz. gold per ton. One carload shipped carried 12½% copper and 15 oz. silver, no returns being made for gold. Another shipment contained 8.7% of copper, 13½ oz. silver, and $2.60 in gold, per ton. Most of the ore at the time of visit was being shipped to Butte, in accordance with a stipulation that the silica should not fall below 90 per cent.

### TABLE OF ALASKAN ALLUVIAL MEASURES.

- 1 pan holds .......... 25 pounds of gravel.
- 6 pans ................ 1 cubic foot.
- 15 pans ............... 1 wheelbarrow.
- 10 wheelbarrows ....... 1 cubic yard.
- 135 pans .............. 1 cubic yard.
- 4 wheelbarrows ........ 1 bucket.

These do not agree exactly. A full pan will hold from 20 to 25 lb., and it requires from 125 to 135 pans to make a cubic yard. A cubic yard is usually estimated to weigh 3000 lb., or 1½ tons. If a pan holds 20 lb. and 150 pans equal a yard, then a cubic yard weighs 3000 pounds. A loaded wheelbarrow will hold one-tenth of a cubic yard; this is the ratio recognized at Fairbanks.

By the use of fuel-oil the management of the Alaska Treadwell mine has reduced the cost of steam power more than $50,000 in six months. The cost, using coal, was $125,021 from October 15, 1906, to May 15, 1907, while from October 15, 1907, to May 15, 1908, the cost, using oil, was $74,262. The total cost of the installation has been $28,680 to date.

### NORTHERN TERMS.

Written for the Mining and Scientific Press
By T. A. RICKARD.

Each mining region has its own local terms, originating from the inter-play of peculiar men and peculiar conditions. Some of these terms are expressive; indeed, they may be so expressive as to become a necessary part of a telling description. Other terms by their wide applicability become serviceable in regions beyond the place of their birth and pass into the linguistic heritage of our race. Others again are merely the vulgarisms of the moment or the provincialisms of uneducated men, and the sooner they are thrown over the scrap-heap the better.

Owing to the unusual climatic and geologic conditions of the North, the traveler to the Yukon and Alaska will hear many terms strange to him. Some of these are vivid. For instance, the country beyond the coast range and within the heart of the wilderness, is called the inside, as distinguished from the rest of the world, which to the dwellers at Dawson or Fairbanks is the outside. In southeastern Alaska they have even finer distinctions; anyone going from Juneau to Seattle or to San Francisco goes below, while should he sail for Seward or Valdez he leaves for the westward; so that the inside, the outside, the westward, and below have meanings in which are hinted the migratory habits of a frontier people.

The arctic moss that carpets the frozen face of the northern wild is called tundra. It is a Russian word and came from Siberia. Against one word I rebel, in vain; namely, muck. The dirty blanket of frozen mould that covers the face of the arctic North is called muck. Under a few inches of dull green moss there is a thickness, varying according to locality and exposure, of ice, in which are embedded fragments of roots, moss, mould, and rock débris. In a temperate climate this would mean a layer of soil; in the North, it means a much greater thickness of black ice, which thaws to a liquid mud. Fully 60% of the muck is water, the remainder is mostly organic material that is light enough to float. It is present everywhere: and as it is ubiquitous in the topography it is also omnipresent in speech. There is no synonym to replace muck; mud will not do, for it is not mud; mud is moistened earth; loam, soil, mould, and the like do not express the frozen condition. It is true muck signifies nothing to those who have not been in the North, but to a sour dough or old timers, it has a world of meaning, for it is the one great natural obstacle against which he has fought time and again. Muck has come to stay, simply because there is no substitute available.

'Sour dough' and 'cheecheako' are complementary. 'Sour dough' is the emblem of the seasoned frontiersman. Being unable to procure yeast, the prospector or woodsman carries a little yeast filled with sourdough-batter; with this and by the addition of a little baking soda, he starts the leavening of his
bread, in the form of pancakes, or 'flapjacks.' The men of the North will allow the lump of some dough to freeze and as the stock is diminished they add flour and water, mixing the mass, so that it performs for them the function of yeast. 'Cheechako' or 'chicchoo' is probably of Kamanka origin. 'Chon' or 'chee' means 'new' and 'chaco' or 'chiko' means 'to come'; a 'cheechako' is a newcomer. The term corresponds to 'tenderfoot' in the West and 'new chum' in Australia. It is a word from the Chinook language, a jargon composed of derivatives from English, French, Indian, and Kamanka. Long before the Russian or the American controlled Alaska, there was trade between the Indians of the Pacific coast and the islanders in the South Seas. But that is another story.

'Mish' and 'musher' are distinctively Alaskan. They are Chinook words of French origin, for there is good reason to believe that they were corrupted from march and marcheur. These words are an inheritance from the old voyageurs who came north up the Mississippi and westward from Quebec into the Northwest. A 'musher' now means a wandering prospector. The dogs are told to 'mush,' and the mothers of the North tell their children to 'mush on.'

The last is probably a corruption of marchone.

The men who undertake to work a claim on a royalty, paying the owner a fixed proportion of the gold obtained, are called 'lay-men,' and they are said to have a 'lay.' This term must have been borrowed from the whalers, for in the whaling business every member of the crew receives a share of the profits, called 'lays.' In Cornwall lay-men would be called 'tributaries'; in Nevada they are called 'lessees,' and they ought to be termed 'lessees.'

Next we come to technical terms. A river is said to have a right and left 'limit'; here 'limit' corresponds to bank or border. The right limit is on the right going down-stream. The width of gold-bearing gravel rich enough to be mined is called the 'streak'; this is an abbreviation from 'pay-streak.' It should be further abbreviated, namely, obliterated. 'Streak' is not descriptive, to say the least, for the gold-bearing gravel may exist as a deposit half a mile wide, and even when smaller there is no connotation of narrowness. In vein mining the 'pay-streak' is the width, usually small, in a large lode, that is rich enough to be mined; thus a lode 6 ft. wide may have a pay-streak 2 ft. wide, the other 4 ft. being discarded. A 'streak' is a thin vertical layer, as a 'scam' is a thin horizontal stratum. The gold-bearing silt that constitutes the 'streak' of the Alaskan is from a few inches to a few feet thick and it lies on the creek-bottom like a broad ribbon, the width of which may range from a few feet to a thousand feet or more. The word 'streak' suggests none of these characteristics. It would have been better if the first half of 'pay-streak' had been retained, for 'the pay' has some significance in gravel mining. In Australia the central and rich portion of an alluvial channel is called the 'gutter.' but this term does not commend itself. For 'streak' in its Northern significance we have many synonyms, such as the 'channel,' 'gold-bearing gravel,' 'pay-gravel.' It is a relatively thin layer of rich material lying upon the creek bottom, under an overburden of valueless gravel, debris, and muck.

In the 'drift' mines the terminology is woefully confused. 'Drifting,' as a word to describe the driving of galleries along the bedrock of an alluvial deposit, is an old term borrowed from California. It has won a firm place in technical literature, but underground on Esther creek or on Cleary you will hear curious applications of terms. Thus the main drift will be referred to as a 'tunnel,' the excavation or stope will be labeled a 'drift,' and you will hear of the danger of losing the 'face' by reason of a cave. A 'tunnel,' properly defined, is an opening from daylight to daylight, as in railroad engineering. 'Drift-mining' depends essentially on the digging of 'drifts' in a gravel deposit, therefore 'tunnel' is particularly out of place. The stope or excavation made along the bedrock to a height of six or seven feet may well be called a 'room,' borrowing an expressive term from the coal miner. It seems a needless risk of confusion to call this excavation a 'drift' in a 'drift'-mine which is opened up by 'drifts.' Words gain in utility by being given specific duties.

The miners at Dawson will talk about 'false bedrock'; indeed, I have heard engineers use this term. Bedrock is bedrock; what is meant by the above quoted localism is 'false bottom.' In gravel mining the gold may lie on a layer of clay or sediment at some distance above the true rock surface on which the whole alluvial deposit lies; such a sub-stratum is called a 'false bottom' because it serves as a 'bottom' on which the gold is spread, and a 'false' one, as compared to the real basement of the gold-bearing deposit. 'Bedrock' and 'false bottom' are complementary terms. The drilling of a series of holes across an alluvial deposit is called 'cross-cutting.' This term has a prescribed use in vein mining, and it seems a pity to twist it to a new duty, for which it is not adapted.

The first claim on which gold is found on any creek is called the discovery claim, or briefly, 'Discovery.' Other claims located subsequently are numbered according to their relative position above or below the discovery claim, so that the third claim down-stream is called No. 3 Below Discovery, and the tenth claim up-stream from the discovery claim is called No. 10 Above Discovery. The claims in the Yukon now extend for 500 ft. along the course of the creek; formerly they were smaller. In Alaska they are usually 1320 ft. lengthwise along the creek and 660 ft. across, making 20 acres. Hence the number in the name of a claim will give an idea of its relative position, although the accuracy of the deduction is apt to be spoiled by the existence of intermediate fractional claims. If the discovery is made at the point where a branch creek joins a main valley, there will be no claims below 'Discovery.' Thus we speak of 'No. 5 El Dorado.'

'Frost' is used to designate frozen ground; thus, the drift miner thaws 'the frost' and the dredge superintendent bunks against 'the frost,' especially if he is reckless. Mining in the North is the conquest of 'the frost.'
MINE SAMPLING DEVICES.

By Harley E. Hooper.

The two devices herewith described have been frequently used by me when engaged in mine sampling, and as they have proved great conveniences, a brief account of them may be of use to other mining engineers.

Sampling Chair.—This is a form of the old hanging chair modified to ensure greater stability, and to allow the operator to work in hard ground with both hands. The projecting arm at the back of the seat may be made of any length to suit the winze requiring sampling, or a new one may be made in a few minutes at any mine when the winze to be sampled happens to be of an odd size. Four short ropes, attached in the usual way to the seat, are made fast to the windlass cable. With the thumb-screw slackened and the tail-piece well in, the sampler is lowered until the desired position is reached; he then works himself close up to the face by pushing the tail-piece out with one hand and using the thumb-screw with the other. The two forward projections may be dispensed with, if not desired.

 Catching Bag.—This was used for some time apart from the 'chair' for sampling high up the steep face of a stope, or at the back of a wet drift, under which a cloth could not be laid. It consists of a semi-circular hoop of 3/4-in. round iron, to which a canvas bag is carefully sewn so that it falls vertically from the straight edge of the hoop. The stitching should be done carefully round the bottom edge, and if any doubt exists as to any of the sample being retained in the bag, it may be used with the reverse side each time. The semi-circular side will be found convenient for getting into ordinary depressions, and the straight side for regular faces, while for acute depressions the corners can be used. In general mine sampling this device will be found invaluable. Using it in conjunction with the chair, a raw-hide belt lace is attached to the middle of the curved side of the bag and to the rope about 3 ft. above the chair. This holds the bag horizontal while the inner edge is resting on the sampler's knees. The bag may also be used to hold moils, hammer, etc., and when the operator desires to ascend he simply pushes it off his knees when, from its shape, it hangs closed up. With an acetylene bicycle-lamp suspended under the left arm by a strap over the right shoulder, I have sampled numbers of winzes rapidly, accurately, and cheaply with the above devices. A bicycle-lamp I find to be preferable to the regulation acetylene mine-lamp for this work.

The septic tank, for treatment of sewage, is a comparatively recent development, and was introduced about the same time by two experimenters working absolutely independently, one at Champaign, Illinois, and the other at Exeter, England. It is, in effect, a sedimentation basin, so designed and operated as to lessen the sludge deposit by dissolving a portion of it and by reducing another portion to gaseous form. This reduction or hydrolysis of the sludge is brought about by anaerobic bacteria, which work in the absence of air and are thus directly opposed in character to the aerobic bacteria or nitrifying organism of sewage farms, intermittent filters, contact beds, and percolating filters. Since inorganic matter is not acted upon by the bacteria, its exclusion from the septic tank is desirable. To this end, small grit chambers are provided, through which the sewage passes on its way to the septic tank, and in which the sand and other mineral matter sink because of their greater specific gravity. The inlet and outlet of the septic tank proper is usually submerged, since in the presence of air the anaerobic bacteria would be replaced by aerobic. The tanks are made long and narrow, thus affording time for sedimentation, and have a sewage depth of from 6 to 9 ft. The best form is probably an underground or partly underground, air-tight, light-tight, concrete chamber, large enough to hold approximately one day's sewage flow. It should be provided with baffle-boards, so that the velocity of the current is small. The sludge collecting in the tank must be removed occasionally. The effluent from a properly constructed tank may be discharged with impunity into any stream not used as a source of water supply. A septic tank should make an ideal system of disposal for a small town or community having a limited water supply and no natural water-course into which raw sewage can be discharged.

The largest concrete arch in the world has just been opened to traffic at Philadelphia. The span of the main arch is 233 ft. and the rise is 70 ft. 3 in. Although the arch rings are of plain concrete, steel floor beams are used in places, and also minor reinforcement to guard against internal stresses.
HOSTOTIPAQUILLO AND THE LERMA RIVER.

Written for the MINING AND SCIENTIFIC PRESS
By EZEQUIEL ORDOÑEZ

In view of the geological features and the great extent of the veins, Hostotipaquillo is one of the most important localities in the western Sierra Madre, Mexico. It lies within the District of Tequila of the State of Jalisco, in a mountainous region that is cut by the canyon of the river Santiago or northwest of Guadalajara to Hostotipaquillo, has excavated its own bed, almost at the southern foot of a group of mountain ranges running northwest and appearing to terminate in the central plateau. Only a few of these ranges seem to be continuous farther south, and therefore the Sierra Madre presents different widths to the north and south of that river in the District of Tequila. The width of the Sierra Madre is so far reduced to the south of the river that it were not for the northwest prolonga-

Lerma, and is therefore in the region of high mesas, deeply carved by tremendous erosion. In no part of the country can one better appreciate the true physiographic character of the western Sierra Madre. The plateau has been the result of the piling of volcanic material upon an ancient land surface. There is now a marked difference in the two sides along one portion of the canyon. The south side, which belongs to the central plateau, is 3400 ft. above sea level, while the opposite side, which belongs to the Sierra Madre, presents elevations that almost reach 6500 ft. above the sea, but on the plateau, long sierras rising above the plains reach and even exceed that elevation. The Santiago river, from the
tion of the Etzatlan ranges and the great barraneras de Mocteltite, the Sierra Madre would be interrupted near the parallel of 21° 30' north latitude, to re-appear subsequently farther south and with greater vigor in the regions of Pijuntos and Mascota. If that interruption had been established there would have been a convenient pass in central Mexico to reach the Pacific coast, by only crossing a series of high tablelands from Guadalajara to Tepic.

The Cananea, Rio Yaquita & Pacific railway, which will shortly connect the Mexican Pacific coast with the great central plateau, by way of Tepic and Guadalajara, has encountered great difficulties in running through the narrow pass in the Sierra Madre
to the northwest of Etzatlán. Although the final route through that region has not yet been decided, it is important to notice that the railroad will not pass far from the town of Hostotipaquillo. It is said by railroad men that a line to cross the ranges and the barranca will require many bridges and viaducts, which in the aggregate will amount to one and a half miles, as well as several tunnels aggregating about the same length. It is well known that the western support of the great central plateau of Mexico is essentially eruptive in character, and that the mineral resources of that region have been exposed by deep erosion, because the high western edge of the central plateau was first covered with rhyolites and dacites that formed high mesas overlying the veins. These veins, which run through the underlying andesites, diorites, and Tertiary granites, would never have been revealed if there had not been carried off toward the coast a formidable volume of the acidic younger material that composed the marginal mesas. At present these mesas in the Sierra Madre are broken in every direction by deep ravines in which numerous veins appear.

The Santiago river is one of the most important in Mexico, with a length of nearly 1200 kilometres, having its rise in the eastern corner of the high valley of Toluca from several springs that together form the muddy lakes of Lerma and Almoloya. This river bears the name of Lerma to the point where it discharges into lake Chapala, at about the middle of its course. Chapala was, in former times, a wide valley drained by the river, but at the beginning of the Recent era, a barrier of basaltic lava converted the valley into a large basin. After that the basin was broken by erosion, resting the river to the ancient channel on its way to the ocean. In cutting its way through the Sierra Madre, the Santiago river exposed a mineral territory not less than 30 miles long in the neighborhood of Hostotipaquillo, the outcrop of veins ribbing the mountains in their slope to the river bed. In all this large territory are distributed the groups of mines called La Cobriza, Cinco-minas, Santo Domingo, San Pedro Análeo, Mina Grande, Quebradilla, as well as those of El Favor, San José, San Francisco, Cabrera, La Castellana, Refugio, Jora Vieja, and others not situated on independent groups of veins. The mineral system is seen to extend without interruption where erosion has already washed away the overlying strata newer than the veins. In this same region, and at short distances apart, are other famous mining districts, such as La Yesca, Bolaños, which, like some of the former, belong to a different political division. The town of Hostotipaquillo, the chief seat of the municipality, is outside of the mining area, as it is situated on the edge of the central plateau where it descends into the canyon. The geological structure of the Sierra Madre and of the central plateau is clearly and simply exhibited in this region. It is seen that the central plateau owes its elevation, as is well known, to the successive heapings of volcanic rocks upon older eroded lands. In this connection, any one could view a beautiful landscape from any of the high peaks that lift their heads about the right border of the Santiago canyon north of Hostotipaquillo. A trip to this region for this sole purpose would be worth the trouble. From a great height, supported by uniform steep slopes, the geologist contemplates, over the horizontal line of the plains that form the central plateau, the volcano of Tequila with a great lava mass crowning its summit. The immense cone of this high volcano appears to repose on a large platform of lava, which is bathed by the waters of the Magdalena lake. The nature of the ground is as suggestive as the landscape; rhyolites and dacites are the constituents of the mesas, and on such material rests the entire volcano of Tequila. These rocks lie on the Miocene andesites, which are distributed through granites and diorites. In these andesites are found the veins along the lower level near the river and in the high hills in the neighborhood. The mountains are also frequently crowned by remnants of rhyolite mesas in the form of bluffs. In the steep walls of the canyon are found blocks of columnar basalt in the form of cliffs and cornices; these are the remains of a basaltic plain over which the present river flowed, 1200 ft. above its present bed, and for a distance of no less than 50 miles.

The Río Grande de Santiago has three times re-excavated its own bed in its passage through the Sierra Madre. The river first started by flowing through a large valley bounded by mountains of eruptive rock, because it must be stated that the rhyolites that formed the mesas did not spread over prolonged andesitic sierras, but over independent massifs close to each other, each with its own history of volcanic evolution, although many of the massifs were synchronous. The Miocene valley became continually deeper by erosion, and by displacements due to faults along the dikes so numerous in the mining district of Hostotipaquillo. In the Pliocene era, the great overflow of rhyolite constituting the mesas, filled the basin of the rivers and interrupted the course of the waters, which soon commenced to run again over the mesas, filled up the basin of the river and interrupted the course of the waters. These soon commenced to run again over the mesas as well as underground, following their old channel. Near the coast, the river precipitates itself in falls and rapids, which continually work backward, as has been done in the east by the falls of Juanacatlan on the same river near Guadalajara. This waterfall, called the Niagara of Mexico, exists where the great stream ceases to serve agricultural uses and is converted into a source of motive power. The backward erosion of the waters, assisted by movements in block, have eued by re-establishing the old river bed, for the second time, in the form of a gorge with cliffs, afterward becoming gentle slopes. Lastly, this old valley has become the scene of a new geologic change. The uniform slope of the bottom favored the flow of a stream of basaltic lava many miles long and 100 to 300 ft. thick. The erosion cut through and brought down these basaltic masses, allowing the river to return to its old bed. This third period of erosion in the Pleistocene and Recent eras, appears to have been more intense and
prolonged than the two earlier, seeing that after the waters reached their former bed, they have continued their work of excavation, so that it is now 1000 ft. lower. The photographs given herewith will afford an idea of the different phases of this cycle of geologic and physiographic changes.

In this brief history of the Río Grande de Santiago no mention has been made of the period in which the veins were formed; this probably was immediately before the appearance of the rhyolites forming the mesas. Nor has mention been made of the phenomena connected with the appearance of the dikes, some of which are older and some newer than the veins, or of the fluctuations of surface-elevation on a large scale in the Sierra Madre.

The mining region of Hostotipaquillo has been worked over since the commencement of the colonial period, in spite of the rough character of the ground, of the vicinity of warlike Indians in earlier days, and of the entire absence of roads. The last mentioned difficulty exists even at the present time. In the year 1804, Humboldt refers to the vicinity of warlike Indians in earlier days, and of the entire absence of roads. The last mentioned difficulty exists even at the present time. In the year 1804, Humboldt refers to the Hostotipaquillo mines as celebrated, and in the reports presented by the Mining Deputation of Hostotipaquillo to the Provincial Mining Board, in 1824, ample data with respect to the old mines denominated La Famosa, Desabada, El Refugio, Mololoho, El Tabor, La Espada, San José, Quebradilla, Mina Grande, and others were given. Some of these old mines are now undergoing development with large capital in the hands of companies, mostly American.

A complete list of all the companies now contributing to the activity of the district cannot be given, but several are worthy of special mention. The Cinco Minas property, belonging to Martinez and Cardenas, has under development four or five mines. The property represents an approximate value of $500,000. Part of the ores from the Cinco Minas are treated in the Hacienda de Santo Tomas by the patio process. The El Favor Mining Co. operates an extensive property, of which the El Favor mine is the chief. Some of these mines show ore to the value of several million pesos. The Company is planning the erection of a large concentration and cyanide plant in which it will treat its abundant supply of low-grade ores. It will utilize a part of the water-power to be developed by the plant of the San Pedro Analee Co. The Cabrera group of mines belonging to the Virginia Mining & Milling Co., has been producing from the Cabrera mine for many years. The company is now erecting a concentration and cyanide plant to have a daily capacity of 200 tons, and will obtain power from Santiago river. The mill will be erected close to the river bank, and the ores will be brought down from the mines by a cable tramway.

The San Antonio Mining Co. is operating the San José, Las Palomitas, San Antonio, and other mines. It is also operating the small Socorro mill, which is one of the oldest in the district. The San Antonio mill has 10 stamps, partly driven by electricity. The process employed is the patio, and the tailing is concentrated in the old Mexican way. The Jalisco Mining Co. has the Mercedes, Doña Emilia, and other mines close to the old Mololoho and Humblo mines. Work is being pushed by an American company in the famous Casados mine. The exploratory work recently started has led to the discovery of a large quantity of ore. The Company is erecting a concentration and cyanide mill, besides exporting high-grade ore. The San Felipe Mining Co. operates...
a mine near the village of Jecotlan. It also possesses a small concentration and cyanide plant, which is equipped with stamps, Bryan mills, and other modern machinery. The Santo Domingo Mining Co. has operated an extensive group of mines, and completed considerable development work with the help of machinery. The principal mines operated by this Company are the Santo Domingo, Esperanza, Nombre de Dios, and El Favor. It is said that the Company has temporarily suspended work. The Castellana mines have for some years past been worked successfully with English capital. They now have a mill, driven by electric power, with a capacity of 40 tons per day. This Company utilizes a small part of the waters of the Santiago river for motive power. The Cia. Minera de San Pedro Anacleo operates an important group of mines on the right bank of the Santiago with satisfactory results. Some of the mines in this group are considerably developed. The San Pedro mill has six stamp-batteries which crush 60 tons per day. The ores are treated by the patio process, although with rather high losses of silver.

As a general thing all the mills in the Hostotipaquillo district which treat the ores by the patio process give poor returns, as these ores are not adapted to that treatment. The cyanide process will give better results supplemented by concentration. The San Pedro Anacleo Co. has undertaken an important work in the construction of a dam 300 ft. long across the bed of the Santiago river, creating a fall of about 25 ft. Three turbines will be set up to handle a large volume of water and develop 1500 hp. in an electric plant. The construction of this dam across the river reflects great credit on the builders and on the company. They have had to overcome enormous difficulties and incur heavy expenses. When the power plant has been installed, the San Pedro Anacleo Co. will re-construct its mill in accordance with modern principles.

Carlos Romero, of Eztatlan, Jalisco, is the owner of an important group of historic mines, such as Albaradon, La Famosa, Deseada, La Espada, La Quebradilla, La Desembradora, and others. He was formerly the owner of the Mololoha mine, which is famous in local history. The mining region of Hostotipaquillo already involves a valuation of nearly $35,000,000.

The veins in this region traverse aedosite, dacite, and seldom diorite, and it is not a rare thing to find the veins also in breccia and in aedosite tuff. As a general rule, the veins are wide and continuous, especially in the eastern parts of the district, where veins are found with a width of 34 ft. The matrix is quartz and celestite. Large bonanzas were found in the old mines, but the dissemination of the ore throughout the veins gives this district special importance. Its future depends on the utilization of concentration and cyanidation. As a general rule, the ores carry little gold, the most valuable mineral being silver sulphide, sometimes accompanied by galena, pyrite, and blende. There are also small quantities of copper ore, carbonate near the surface, and chalcopyrite below. In the oxidized zone, where secondary modifi-

Concerning the source of ground-water in California, W. C. Mendenhall, of the U. S. Geological Survey, says: "The statement has frequently been made that the underground waters are just as dependent as the surface run-off on precipitation within the local contributing drainage basins, but the tenacity of the oft-asserted belief that these subterranean reservoirs have some other source than local rainfall makes it desirable to repeat the statement with emphasis. Each of the important subterranean basins in southern California is supplied exclusively by the water that falls upon its surface or that flows into it through some tributary stream. Any other hypothesis, as, for example, that the waters from the distant Sierra, or the Colorado river or the Pacific Ocean, may, by underground channels or by seepage, reach the San Gabriel valley or the Pomona neighborhood, is erroneous, and conclusions based on it are wrong and lead to a false policy in the utilization of the ground-water."
THE GASTEROPOD PRINCIPLE.

By James F. Kemp.

*For several years past I have been accustomed to expound to the Journal Club at its annual dinner certain aspects of that all absorbing scientific theme, the origin of ore deposits. Both by constant iteration and by the actual demonstration of working processes before your eyes, ore deposits have now been so positively shown to be dependent upon igneous phenomena, that I have become deadly weary of the whole business, and I realize that my own feelings are merely a faint echo of yours. Therefore I mean to get as far away from them tonight as possible and to discuss a subject that has nothing whatever to do with them.

We all know that in the teachings of paleontology there is one ever-green and never-failing solace for the weary worker in other fields, and although I have only been a cultivator of this branch 'on the side,' so to speak, like the extra lump of sugar in the saucer of the cup of coffee in the restaurant, yet I have for years been pondering one of its profounder problems. Really quite unknown to the membership of the department, there have been two specialists in the gasteropoda among us, instead of one, as you have supposed. Investigation of this problem, the gasteropod principle, has carried me into fields never dreamed of at the outset, and while, like yourselves, I knew it pervaded Professor Grabau from the crown of his head to the sole of his feet, yet I find in addition that it is one of the all-pervasive principles of the universe. In fact, it is the one that manifested itself, almost as soon as there was any universe at all.

First, then, what is a gasteropod; and, second, what is the principle?

On looking up the French word for gasteropod in the dictionary of Messieurs Spiers et Surréne, I found this definition:

"Gasteropodes. Reptiles that creep on their belly."

From this we see that the great gasteropod group embraces the reptiles as well as that portion of the molluscs with which we have usually associated it, and in order that it should embrace the rest of the animal kingdom, all we need is a few more dictionaries. Gasteropods therefore have the possibility of becoming synonymous with the animal kingdom itself, and as exponents of expansion they outclass even the imperialists of our own times and country.

But before this comprehensive conception is reached, let me hasten to set forth the fundamental principle of the gasteropoda, which is the coil or twist that in a greater or less degree runs through them all and is distinctive of them. The gasteropod principle is therefore that one in accordance with which things animate and inanimate develop a twist or whirl or coil.

We find it first exhibited in the nebulas with which since the days of Laplace we have been taught to believe the solar system began. To be sure, there are certain moderns who have tried to upset this bit of folk-lore, notably one iconoclast, T. C. Chamberlin, the planetesimalist of Chicago, but we simply class him with those enemies of the human race who do not believe in Santa Claus or fairies or all sorts of other beings and things without which we cannot well exist.

When the great original nebula began the twisting motion which established the whirl and set the gyroscope of the universe spinning in space, the gasteropod principle asserted itself. Gradually individual centres of rotation were established, each spinning on its own axis, and forming the planets. Each secondary mass revolved around the central parental mass or umbilicus, just as we find the conditions in any snail-shell. Now, if you fix your attention upon any particle of the earth, as for instance the orthoceras, lately discovered as all the world now knows by Professor Grabau in the front pavement of the University library, and if you follow its motion around an axis inclined to the plane of the ecliptic, you will see that it has a spiral motion in space, while the earth goes around the sun. Furthermore, if you take any well known gasteropod, such as the common or garden snail, *Helix alternata*, you will see that there are the same coiled spirals manifested in the shell markings, and all turned around the tube itself. The very revolution of the particles around an axis in a planet is thus strictly in accord with the gasteropod principle.

But I hear someone remark that while the above may apply to those spiral nebulas that we see in the sky, there are other indefinite cloud-like types that have no whirl. The argument is therefore made that when applied in a comprehensive way the gasteropod principle fails. Pause a moment before rashly reaching this conclusion, and reflect that there are gasteropods and gasteropods. There are the shellless slugs and snails, which are mere cloud-like matter, with but the faintest suggestion of a coil, if any at all; yet they are gasteropods, and everything which applies to them is strictly in accord with sound gasteropodian principles.

I have also a somewhat uncomfortable feeling that there may be a sincere planetesimalist among my hearers, who would eliminate the original nebula from consideration, thus destroying the foundation of my contention. But while it is conceivable that some may reject the nebular hypothesis, we do not thereby escape the whirl or rotation. Thus in the second volume of Chamberlin & Salisbury's great treatise on geology, we find the planetesimal hypothesis defined as follows: "In the planetesimal hypothesis the constituents may be molecules, or small masses of any kind moving in orbits about a common centre. They are not primarily controlled by collision and rebound (as in the other hypothesis), but by revolution about their common centre of gravity or some central body, as are the planets today." You see nothing could fit the gasteropod principle better than this. The individual planets grow by the addition of molecules, while they revolve around a common centre. That is exactly the
A method of growth of a coiled gasteropod. The planets, again, are not primarily controlled by collision and rebound. Neither are the gasteropods. Who ever heard of two snails colliding with such force that they rebounded? Susis, moreover, are such solemn looking creatures that they may each be considered a centre of gravity.

But suppose we pass from these early nebulous stages of the globe to the evolution of the constituents. Take South America, for example; we only need to look at its map to see that it is a dextral shell, just beginning its coil, like a deutilium or some such type. Africa is the same, whereas the North and Central Americas constitute a sinistral shell, exactly like physa, with which you are all familiar. Australia is almost exactly the outline of fuessurella, whereas in Asia and Europe are found the counterparts of two or more closely growing crepidulas. All the speculations about a tetartohedral earth—such as have been set forth by W. L. Green of Honolulu or one outlined by the pentagonal network of Elie de Beaumont—fail utterly in comparison with the gasteropodian outlines and analogies.

In later time, when organic life started on the earth, it also fell an easy prey to the influences of the gasteropod principle. Whether we deal with the brachiopods or the cephalopods, or the trilobites, we find them all with a greater or less twist. The trilobites stood out longest, but at the close of the Ordovician they doubled up in repentance as they came to die, just as sinners always do, and the coiled calypne sectera shows the futility of trying to escape the inevitable.

I. cannot stop to recall the wonderful lengths to which in the Jurassic and Cretaceous this principle asserted itself in the amnonites and kindred forms; or in the spiral leaf-scar of the lepidodendra of the Carboniferous; nor in the tusks of the hairy mammoth; but the mere mention will recall them. I must come down to the present.

Thirty years ago or more the Harvard base-ball nine went to Princeton to play a game with the local team. The crimson batsmen lunged furiously at the ball, but in vain. They found that like a thing of life it avoided their strokes. In despair, finally, one of the nine slipped around behind the Princeton catcher, and discovered that the pitcher, in conformity with the gasteropod principle, had imparted a twist or curve to the ball, which only required a sufficiently long journey in the air, to return on itself whence it started. A great dispute at once arose, which characterized the journals of my own school and college days. Some physicists contended that the assumption of a curved trajectory was an impossibility. Others maintained theoretically, and demonstrated practically, that it was not only possible but easy. None, however, have recognized the true gasteropod principle of the twisting curve, until that distinguished and tireless investigator who is now addressing you, discovered it and determined to present it to you this evening.

From the world of sports we turn to the world of morals, and here we deplore the influence of the gasteropod principle. It gives that moral twist to certain characters which is so unfortunate. As in the genus physa, it develops a left-handed or sinistral tendency which it is almost impossible, even by very careful natural selection, to eradicate. Since the time of Pithecanthropus erectus coeruleus, that early moralist among the anthropoid apes, who first established a system of right and wrong for the evolving primates, and who drew a distinction not appreciated up to that time between his cocoanuts and those of his neighbor, Pithecanthropus erectus rassalis, this twist has been much in evidence. The old coiled serpent in the Garden of Eden typified it and imparted it anew to our race. It was later manifested in the struggle of Laocoon and his sons with the serpents, which symbolized the left-handed phase of the gasteropod principle of coils.

But in the world of morals we may not longer linger. We engineers and scientific men deal with problems of matter, and it is the manifestation in these that chiefly concerns us. The gasteropod prince as shown in the screw-propeller takes us speedily across the ocean; as materialized in the log-washer, rescues our iron ores from the clinging but valueless clay; as developed in the ordinary screw, binds our timbers into houses and makes habitable the inhospitable parts of the earth. During our travels we cannot escape it, because the moment when, tired and weary, we crawl into the hotel bed at night, the spiral bed-springs eek out the praises of the gasteropod principle. Speaking of beds, I am also reminded that when we go to Bedloes island and clamber to the expansive brow of the Goddess of Liberty, illuminating the world, it is up the spiral stair-case, constructed in accordance with the gasteropod principle, that we climb, and when we again descend and emerge in the form of human corkscrews, we ourselves also fall in with it. Ah! but that last phrase suggests its culminating manifestation. It is the corkscrew. From ginger-pop to champagne, how could we celebrate our Journal Club dinner without a corkscrew? Where, moreover, would be the great temperance movement if it were not for the corkscrew? Where would we ourselves be, if it had not in our infancy placed at our service the soothing syrup or other equivalent cure for the colic?

Messieurs et Mesdames, with full and grateful heart, I propose the toast, Vive le principe gastéropodien du Monde naturel et civilisé.

Electrolytic production of iron has been applied in making large sheets having a surface like the cutting face of a file. These are later cut up into small pieces and, secured to suitable backing, make separate files. A matrix is prepared by making impressions from a suitable die, revolving roller, or reciprocating tool in sheet of lead alloy, which in turn is mounted upon a revolving drum and suspended as an anode in a suitable electrolyte.

The deepest shafts in the Transvaal are those of the Jupiter mine, 4250 ft., and the Cinderella Deep, 4200 ft. The Jupiter shaft is being deepened steadily.
**MINING AND METALLURGICAL PATENTS.**

Specially reported for the Mining and Scientific Press.

---

A dredge comprising a scow, dredge mechanism mounted thereon, tracks on said dredge, connected dump cars on said tracks and traveling thereon by gravity, gravity locking means at one end of each track and gravity dumping means at the other end of each track, a gravity scoop and operating means therefor carried by the scow, and a prime mover carried by the scow and connected to the said scoop-operating means.

In an ore concentrator, in combination, a table-frame, a plurality of guides pivotally mounted thereon and movable in a plane parallel thereto, blocks movably mounted in said guides and carrying a deck having an ore-concentrating surface, means for connecting said guides in pairs, adjustable levers attached to said frame and each of said connecting means, means for holding said levers in any desired position, and means for reciprocating said deck.

ORE-DRIER.—No. 902,328. Daniel T. MacLeod, Merchantville, New Jersey.

The combination of an ore roasting furnace, a drier mounted above said furnace, a vertical hollow shaft extending through the ore roasting furnace and into the drier, means for rotating said shaft, a pan in the drier situated some distance above the top of the furnace so as to form a channel under the pan, openings in the hollow shaft communicating with the said channel so that the hot air passing through the hollow shaft will enter the drier between the pan and the top of the furnace, and means for feeding material to the drier, with a discharge opening from the drier communicating with the furnace, substantially as described.

ENDLESS-CHAIN BUCKET EXCAVATOR.—No. 901,068. George L. Hurst, San Francisco, California.

An endless chain bucket excavator and elevator, the same including a series of excavating buckets having cutting edges and a series of independent cutting devices having cutting edges arranged to extend directly in advance of and at the same depth as the cutting edge of each excavating bucket, and in the path of travel of said cutting edges of the buckets.

Metallurgical apparatus comprising a closed tank, a filter in the lower portion thereof, a liquid outlet beneath said filter, a mechanical agitator in said tank, sources of supply for pulp, solutions and compressed air, connections between said sources of supply and the upper portion of said tank, and means for closing said connections.

In an apparatus for concentrating ores the combination of a fixed surface, means for feeding powdered ore over the surface, means for continuously feeding a thin stream of liquid over the surface, a movable body having a flexible squeegee edge in contact with the surface sufficiently flexible to pass over the ore while exerting sufficient pressure on the surface to remove the film of water therefrom, means for sweeping the body over the surface in a direction at right angles to the direction of flow of the water to cause the ore to be alternately exposed to the air and to the edge of the liquid.
HOME-MADE CYANIDE PLANT.

Written for the Mining and Scientific Press
By W. F. Birkeme and B. L. Eastm.

The following description of a home-made cyanide plant may prove interesting in showing how low-grade tailing, formerly thrown away, is being treated at a profit by a couple of men, at small cost of labor and supplies, and a trifling initial expenditure of capital. This little plant treats the tailing from the 40-stamp mill of one of the large mines of the Grass Valley district, California. The management of the mine has not felt justified in going to the expense of erecting a large cyanide plant, as the tailing assays only from 40c. to $1 per ton. As the men who put up the plant had no contract with the mine for the tailing, they naturally sunk the least possible amount of money in the enterprise, in view of the precarious source of their supply of material.

The mill tailing is collected below the mill in sluice-boxes, and carried a half-mile down the ravine in V-shaped overhead launders. It is then allowed to flow directly, without previous sizing, into one of a series of five leaching-vats. These vats are each 18 ft. diam. and 5 ft. 6 in. deep, constructed of 2-in. redwood, and hold 40 tons of sand. One charge is obtained in 24 hours. The distributor for the sand was constructed on the ground, and has some special features, having the merit of so mixing the sand and slime that a charge with as much as 20% slime can be successfully leached. It has six arms 7 ft. long and 20 ft. wide; each of these is divided into 12 separate channels, down which the sand flows from a round central sand-box. Each channel comes to a stop before the end of the arm is reached, and a hole is bored through the bottom, through which the sand drops into the vat. These holes are so arranged that the sand is evenly distributed. Hence, there is no need of leveling the vat when it is filled. The surface is almost as level as a billiard table, and solution can be run on at once. Before entering the channels, the sand flows into a round box which is pierced at the bottom with 1-in. holes, through which the pulp spurs evenly. The launder that feeds the sand-box has four large holes, insuring even distribution without packing. Unlike most distributors, this one is lowered into the vat to be filled, and raised gradually by a windlass, a barrel of rocks serving as a counterbalance. A large proportion of the slime is floated off immediately through a system of plug-holes, of which there are three rows, 6 in. apart, the holes being 2 in. diam. As fast as the vat fills, a plug is put in and the one above it is knocked out; thus there is no loss of sand, but the slime has no chance to settle, as might be the case if the holes were only at the top of the vat.

Instead of using the familiar lawn-sprinkling device, the distributor is turned mechanically by a system of old cogwheels and bicycle-chains at about one revolution every 7 min., which is slower than most distributors. The initial power is furnished by a small stream of water falling on a home-made overshot water-wheel. The distributor travels back and forth over the leaching-vats on overhead tracks, and is pulled along by a windlass and wire ropes fastened at either end. The vats are emptied by 'hosing out' the sand through a sluice-gate at the bottom, 6 by 6 in. square. This takes about three hours.

The sand is leached in the regular manner, and receives a 96-hr. treatment. Two strengths of solution are used, the first of about 0.2%; the second is weaker: about 10 tons is introduced at one pumping, about 100 to 125 tons of solution being used altogether. No lime is added. Between each batch of solution the charge is drained for 1 to 5 hr., depending on how the sand leaches. The cyanide consumption amounts to about 0.6 lb. per ton, and the extraction is generally above 85 per cent.

The zinc-boxes are half-barrels, caulked and painted. The harren solution flows into a sump, from which it is pumped direct, after the necessary cyanide has been added, to the leaching-vats. The small Dixon pump, which, being valveless, requires little attention. A 12-ft. wooden overshot water-wheel, constructed on the ground, gives ample power. The precipitated gold is dried on an open hearth-furnace, the zinc being partly volatilized. It is then sent to a local assayer for refining, and sold to the mint.

A natural mound in Texas is remarkable for the great number of rare earth minerals which it contains. It lies in almost the geographical centre of the State, and is locally called Baringer hill. About two dozen minerals are found in the small elevation, less than 40 ft. high and 100 by 200 ft. in plan. Among the more important ones are fergusonite, gadolinite, polyacase, yttrialite, and cryotile. The economic interest in these minerals is due to the incandescence of their oxides on being heated. This property makes them available for use as glowers in gas and electric lamps. Thoria, beryllia, yttria, and zirconia are the most useful minerals employed for this purpose. Until the discovery of the deposits at Baringer hill it was practically impossible to get sufficient yttria-bearing minerals to manufacture mantles for electric glow lamps; but fergusonite and gadolinite, with lesser amounts of cryotile and other minerals containing yttria, occur here in quantities large enough to meet the demand. The Nernst Lamp Co. owns this valuable deposit, but its needs require only the occasional working of the mine. After enough yttria minerals are obtained to supply its wants for several months the mine is closed. Only a few hundred pounds a year are extracted. The geologic island on which Baringer hill stands is interspersed with other mounds and dikes of similar appearance, which have been prospected, but without much success.

Superheated steam causes no chemical change in hydrocarbon cylinder oil below 750° F., according to G. W. Worrall and J. E. Southcomb. The deposits which form consist chiefly of iron oxide, the adhesion of the oxide depending upon the tarry constituent in the oil, the amount present depending on the completeness of the distillation. Further distillation of the oil occurs in the steam cylinder, leaving these tarry products behind.
Steam-Shovel Underground.

The possibility of successfully installing power-shovels in the zinc-lead mines of southwestern Missouri has been considered by many mine owners, and many manufacturers have been consulted in regard to the proposal. To all these inquiries came the reply that it was impracticable. One man in the district persisted in his inquiry until he succeeded in interesting a shovel manufacturer in undertaking a demonstration of the practicability of operating automatic shovels underground. The man who persisted was C. W. Landrum, resident general manager for the American Zinc, Lead & Smelting Co., and the man whom he interested was Capt. R. Thew, of The Thew Automatic Shovel Co., Lorain, Ohio.

In new things perfection is seldom attained at the first effort, and the installation of a power-shovel in the Missouri zinc-lead mines was variously voted a success or a failure by different observers. But to investigators, who look beyond the mere movements of the machine, it was a success from the first. Superficial inspection may have decried it as a failure, only because it did not immediately and materially reduce the number of men required by hand-shoveling, but it has proved a financial success to the company operating it, as it requires cheaper labor and produces a larger tonnage. It is a pronounced success in never failing to supply ore to the mill. By keeping the mill in steady operation the Thew shovel becomes a profitable investment.

The Thew automatic shovel represents the first effort in this district to install a machine for shoveling underground. The American Zinc, Lead & Smelting Co. will soon install a second shovel, and a third is contemplated when the second is in working order. The first machine was a slight modification of a standard Thew shovel, the chief change being the adoption of compressed air in place of steam. The second shovel will be modified and adjusted to local requirements. It will be lowered in height, and the radial reach will be reduced. There are other improvements under way, such as electric motor-cars for haulage to and from the shaft, instead of men or mules.

Standards of color are not so easily established and maintained as are those for distance, weight, strength, and the like. The latter are tangible, and under similar conditions permanent. But color, once established by means of a sample, is subject to change by time and exposure. The mixing of certain proportions of specified color-ingredients does not insure absolute similarity, because of the uncontrollable variation in the elements which make up the mixture. Scientists have long sought a simple means of measuring color and of keeping records of the same, so
that it might be easily reproduced at any time. This has been accomplished in the colorimeter, invented by Frederic C. Ives.

The instrument is convenient, and practically available in the arts and industries. Its simplicity is as marvellous as its ingenuity. At one end of a rectangular box, 18 in. long, are three apertures, covered by primary-color screens of respectively red, green, and blue glass. Each of these apertures is provided with an adjustable shutter, the amount of opening of which, and hence the proportion of the given color, may be read upon a corresponding scale. The resulting color, as a rule, may therefore be expressed as 'red 50,' 'green 5,' 'blue 80.' At the other end of the box is an eye piece, and at mid-length a lens in connection with a wedge prism so placed that the light from the color screens passes through only one half of the lens. At this point is also fixed a mixing wheel consisting of 12 convex prisms so arranged that as it revolves the prisms successively pass through the line of vision. When at rest, either red, green, or blue will appear, according to the position of the lens; but when the wheel is revolved at the proper rate of speed, the independent colors become so perfectly mixed, because of the persistence of vision, that the result is a single even color- impression. The character of this color may be changed through all hues by varying the openings of the shutters for the three primary colors. Results may be kept of each opening as read on the scale. Hence the color can be reproduced at any time by 'resetting' to the same scale readings. Through the other half of the lens can be seen the color which is to be matched, so it becomes merely a matter of adjusting the proportions of the primary colors thrown upon the first half of the lens until both halves are of the same color. Ingenious means are provided for overcoming the effect of the difference in natural lighting, as affected by weather, position of instrument, and so forth. The first of these instruments was installed some months ago at the Arthur D. Littie Laboratory, Boston, where its practical usefulness has been displayed in the every-day work of a large industrial laboratory. It was through Mr. Littie's recognition of the value of such an instrument, and his urgent appeal to Mr. Ives, that the device was perfected.

Commercial Paragraphs.

The National Wood Pipe Co., Los Angeles, advises that it has been awarded a contract for 40,000 ft. of its machine- bonded wood-pipe, for use in the Teague, Texas, municipal water system.

The Cyanide Plant Supply Co., of San Francisco, issues a handsome and useful catalogue, describing the equipment necessary for cyanide plants. Notes on wooden tanks and instructions for erecting them are included, as well as a code for telegraphing orders to the company.

The Salt Lake Hardware Co., of Salt Lake, is proceeding rapidly with the construction of its new warehouse, the foundation and first floor being now completed. The building will be a five-story brick and concrete structure, 165 by 236 ft., and will be the finest warehouse in the entire intermountain country. The building will contain about six acres of floor space, and will afford facilities for handling eight carloads of merchandise at the same time. The company expects to issue a new 2000-page catalogue about next March.

The H. W. Johns-Manville Co. is placing on the market, under the name of 'Leak-No Metallic Compound,' a chemical composition resembling powdered iron. When mixed with water and applied like putty to defects in iron or steel articles it sets and, it is claimed, becomes really a part of the article. When hard its color is similar to that of iron. The manufacturers offer to refund the purchase price in case it fails to stop any ordinary leak in anything made of iron or steel against any pressure of oil, steam, gas, air, ammonia, or water, or to stand any heat or chemicals that iron will stand, when applied according to directions. A neat folder, describing this material, may be had for the asking.

Publications Received.

Any of the books reviewed or mentioned in these columns are for sale or procurable from the MINING AND SCIENTIFIC PRESS.

The volume is primarily a text-book, and is a valuable addition to the already large list of such practical books. The feature of the book is the admirable illustrations, many of which are examples of students' work. Machine sketching is very properly given considerable attention. A complete set of problems, arranged so that they can be used by students without further amplification, makes the book particularly useful for instruction work.

These three volumes of a series are, in the main, reprints of articles appearing in Power, collected and arranged in convenient form for office or shop use. They each contain valuable hints for those using and erecting machinery.

In this edition the whole work has been practically rewritten and brought up to date. The book adds nothing to the already voluminous literature of the subject, but is nevertheless a clear presentation of the different phases of road building materials and methods. Illustrating matter is particularly conspicuous by its absence.

This is intended for the use of the prospector and mineral collector. It is a valuable little book, full of useful data and well indexed. The printing is good and the volume is conveniently bound in flexible morocco.

Catalogues Received.

Edward Christian, Mansfield, Ohio, has recently issued an attractive illustrated catalogue of drilling machinery and equipment.

The Canadian Rand Co., Montreal, Quebec, has just issued its catalogue of steam and power-driven air-compressors. It contains a complete description of the theory and construction of compressors, and is a valuable addition to any library of trade publications.

L. Vogelstein & Co., New York give the following figures of German consumption of foreign copper for the months January to September, 1908:

<table>
<thead>
<tr>
<th>Tons</th>
<th>Imports of copper</th>
<th>122,555</th>
<th>Exports of copper</th>
<th>6,393</th>
</tr>
</thead>
<tbody>
<tr>
<td>Consumption of copper</td>
<td>116,162</td>
<td>The consumption during the same period in 1907 was 57,480 tons. Of the above quantity, 112,529 tons were imported from the United States.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
EDITORIAL.

UNDoubtedly the talk of sudden improvement in business since the election has been overdone. The daily papers have aimed to create a sensation, and some brokers have been willing to wink at anything that stimulated gambling. No sudden revival has occurred, but something more lasting, namely, a steady resumption of industry and a renewal of confidence in the future.

OUR LONDON CORRESPONDENT gives information concerning the share-holdings of the Consolidated Goldfields of South Africa. It appears that this important corporation holds large blocks of stock in Yuba Consolidated; Oroville Dredging, and United States Smelting, Refining & Mining. The holding of 12,589 shares of the smelting company’s stock is interesting; the total capitalization being 150,000 shares, the block of stock held by the Consolidated Goldfields is not controlling, but it is bound to be influential.

ROCKEFELLER testified that he started in 1866 with a capital of $6000 and he now controls a business that has earned $570,000,000, paying $40,000,000 in dividends last year, while earning twice as much in that period. Equality of opportunity is a glorious thing, but it may well be asked whether in this case it has not become the opportunity to prey upon others, the unrestricted chance to be essentially anti-social, the power to corrupt the fountains of justice and legislation.

LEAD is in danger of losing the protection of a high tariff. The congressional committee on the tariff will hold its last meeting at Washington on the 25th inst, and mine operators are afraid that a reduction will be recommended. At present the duty is 2½ cents per pound on pig lead and 1½ cents on lead in ore. As lead is selling at 4.35 cents at New York and 1½ cents at London, it is obvious that its market value would be cut in half by the removal of the protective tariff. This violent measure is unlikely, although some reduction is probable. Of course, there is a vigorous protest from those that will suffer. In the Coeur d’Alene mass meetings have been held, and in Missouri public interest is equally keen. Touch the pocket nerve and there is an instant response. That is why the tariff is let alone so long. It may be a local question, but so many local industries are involved that the issue becomes general. There are others. In Canada the Government gives a bounty on lead produced from the mines of British Columbia; this retaliates on the American tariff and bespeaks another form of artificial regulation of production. Should the tariff be lifted on this side, the bounty would probably be
denied on the other side of the international boundary. It is a broad subject and yet a delicate one. We disbelieve in special privilege to anyone, but we are sorry when such privileges are denied to our friends.

A National Newspaper.

In our last issue we referred to the baleful influence of the press of San Francisco in misleading public opinion and obstructing justice. When Thackeray started the Pall Mall Gazette he stated that it was to be a paper edited "by gentlemen for gentlemen". Our local newspapers, like those of many other American cities, are owned by men without character and edited by men without principle; in short, they are in the hands of men without the conception of citizenship. The power for evil exercised by Hearst and Brisbane through seven polluting papers in five American cities should suggest the tremendous influence for good that could be exerted by a national newspaper, issued simultaneously at New York, Chicago, and San Francisco. Such a paper would be non-partisan, giving the views separately of the different political parties; such a paper would give literary, dramatic, and scientific criticisms and comment that would be reliable, because written by experts: such a paper would have a few pages of local news attached to a mass of stimulating, accurate, and interesting information on the topics of the day. What university or half-dozen universities would exert so beneficent an influence? We are of the opinion that if today the University of California were closed and Mr. Benjamin Ide Wheeler, the president, were to devote himself to the editing of a morning newspaper, aided by the members of the faculty, and also if Stanford University were closed and Mr. David Starr Jordan, the president of that institution, were to edit an evening newspaper, with the help of the Stanford faculty, the community would gain immensely by the change. In this industrial civilization the average man reads a couple of books in a year, and at least two newspapers each day. Consider for a moment the mass of misinformation absorbed by the average citizen. Did you ever know a daily paper—except the four or five specified in our last issue—that could say anything about a subject on which you had accurate knowledge without that paper committing the most absurd blunders and mis-stating the facts in a perfectly puerile way? A youth—in California, for example—goes to the University, perhaps to a beautiful white building donated by the Hearst estate, for three or possibly four years; then for thirty or forty years he surrenders his mind every morning, and perhaps in the evening also, to the perverting and demoralizing influence of a Hearst paper, or to something even worse, such as De Young's Chronicle. Rich men have given marble palaces for the education of the youth of America. Will not some big-souled man give a few millions to endow a great newspaper? "It would not pay." We think it would, after a time. The best papers in America are profitable enterprises. And if it did not pay, what of that? Do universities pay? Not in shekels. They are not expected to be self-supporting; they are endowed by the State or by its citizens. To be independent, such a paper should not be dependent on its advertisers, while becoming an incomparable medium of publicity. Thus a national newspaper might be endowed with $10,000,000 by a successful miner or manufacturer, rich beyond his necessities and desirous of enduring fame. And better still, let some natural leader of the people organize such a newspaper enterprise, asking for the support of the mass of plain sensible citizens—those the god of whose idolatry is not prosperity alone. If our description of existing conditions is correct, and if we do not over-estimate the influence, for good and bad, of the press, this idea will find root, and from it someday will grow a benefaction farther reaching than any library and more educating than any university.

Dredging in the North.

In this issue we publish a detailed description of dredging on the Seward Peninsula; this supplements the articles previously published concerning dredging in the Yukon Territory. Most of our readers will be surprised to learn that fully 65 dredges have been built in Alaska and the Yukon, although it is fair to say that fully one half of the number represent the projects of ignorant people excited by the stories that stimulated the feverish undertakings of the boom days. These 65 dredges cost $3,000,000, and the various enterprises they represented must have absorbed, in all, at least $6,500,000. Out of the flotsam and jetsam of the boom period there survive one or two little dredges that are making money on rich ground; in addition, a number of modern first-class dredges have been built within the last two or three years; today there are 12 dredges that can be labeled as technical and commercial successes. Twelve out of 65 is a large average, as human enterprise goes, and affords encouragement to further application of this method of mining. Assuredly the modern dredge is a wonderful machine in its ability to dig into rock. In the north the soft schist, constituting the prevailing bedrock, or the weathered limestone, such as exists in the river-beds near Nome, is cut like cheese by the hardened lips of the buckets, and is raised to the surface together with the gold enmeshed within the crevices of the rock. But there is one thing that a dredge cannot do, save at its peril, and that is to attack frozen ground. The gravel that is cemented by ice is no more suitable for dredging than is reinforced concrete. Occasionally a dredge may be able to remove a small patch of ground that is frozen not too completely and not too solidly, but as a rule the worn lips of the buckets, the shattered spud, the cracked gear-wheel, and the sad disarray of the whole mechanism serve as eloquent witnesses of a conflict with Nature that proved disastrous to the invention of man. Nor is it necessary to incur the risk of destruction; the frozen ground can be avoided and left to the mitigating hand of summer, to be attacked later in the season; or it may be thawed artificially by the use of 'steam-points', as described in our issue of September 12. By strip-
ping the overburden of moss and dirt, which covers the ground like a dirty blanket and affords an insulating protection to the underlying ice, it is possible to use the seasonal thaw of summer to an extent varying with each locality and each season, but sufficiently to lessen the expense of artificial thawing with steam. At this time, although methods are undergoing rapid evolution in adaptation to new conditions, it is possible to state that the cost of dredging in the North ranges in different instances from 18 to 32 cents per cubic yard, even with single dredges burdened with disproportionately large charges for power. We shall discuss the question again shortly, with a view to arriving at some idea of the possible extension of this form of mining in the North, but even at this stage of the enquiry it is obvious that there is much encouragement. Of course, there have been failures, and many of them. If people play the fool, they must not expect miracles to happen to extricate them from the consequences of their folly. Dredges are built without testing the ground by drilling, or the drilling is done by the vendee of the property, or it is done in good faith, but carelessly. Then, instead of getting a machine of tried efficiency, the intending operator buys either an old second-hand contraption or undertakes a new venture and builds something designed on lines of his own devising, or on those of some similarly inexperienced person. Having got a dredge, even occasionally a first-class dredge, the mistake is made of consigning the charge of it to someone inexperienced in this kind of mining—to an electrician, a millman, an ordinary mine superintendent. The result is a smash, enforced idleness, loss of revenue. If you want to learn how to do things aright, study the story of the Three Friends dredge; if you are to be deterred by a warning, read of the blunders made by the owners of the Bourbon Creek dredge. These are typical instances, the latter especially. The worst of all waste is the waste of experience.

We have spoken of the cost of dredging in the North as ranging from 18 to 32 cents in ground not requiring steam-points. In such ground it will be possible, by employing at least two dredges on one operation and utilizing electric power generated from water, to reduce the cost so as to make it 10 to 15 cents per cubic yard. The cost of fuel is the big tax on profits. In ground requiring special treatment, by stripping and steam-points, the cost is now 20 to 25 cents, even operating on a large scale; it will be reduced to an average of 15 to 20 cents per yard. By way of comparison it is proper to quote from the report made four years ago by Mr. C. W. Purington, who described the methods then in vogue in the gravel mines of Alaska, contributing a memoir that has proved one of the most useful published by the United States Geological Survey. Mr. Purington gives 30 cents as the cost of dredging in thawed ground and 80 cents in ground requiring artificial thawing with steam-points. He was an unprejudiced observer, and it may thus be inferred how great has been the progress in this branch of mining, when the cost today can be stated by an observer equally unprejudiced to be 15 cents in unfrozen ground and 25 cents where thawing is needed. The decrease seems most marked under conditions presenting the greatest obstacle, for thawing has been improved, by better appliances and more system, until it has ceased to be the crude operation of the early days. As against a high cost there is balanced the unusual richness of the gravel in Alaska and the Yukon. Ground yielding 60 cents to 1 dollar per yard is not uncommon, and there will be ground dredged that will yield 2 dollars per yard for a month's run. The increased cost of operation is more than compensated by the unusual richness of the gravel. An engineer would rather tackle the difficult problems presented in the North with gravel at 50 cents or 1 dollar per yard, than the 10 to 15-cent material offered in localities more favored by nature. At Oroville the average yield is 15 cents and the average cost 6 cents per yard. The ratio of profit is no better than it is in the North, and while the operating cost is near the irreducible minimum in California, it is close to a descending maximum in Alaska and the Yukon. There is offered today a splendid field for the exercise of ingenuity and skill in the exploitation of gravel deposits of unusual richness and extent.

**Gossip**

Gossip reaches us from New York in regard to the ownership of The Outlook, a weekly periodical with which the President is to become connected. Whether Mr. Stillman and the Standard Oil control this publication, or whether they do not, the gentlemen on Wall Street have cackled at the idea of a contract between Mr. Roosevelt and a publishing concern that might be controlled by the sinister agency he has attacked. On the whole, the evidence available indicates that no "malefactors of great wealth" own The Outlook, but well meaning persons of respectable character. On slips asking for a subscription to their paper, the publishers state: "The Outlook Company has the honor to announce that Theodore Roosevelt, President of the United States, will on March 5, 1909, become a member of the editorial staff of The Outlook, which will hereafter be the exclusive channel for his writings on Political, Social, and Industrial Topics." This is a regrettable performance, for the exploitation of the presidency in the interest of journalism is not in good taste. Why could not the participants have waited until after the President's term had ended? It may be that some of our readers consider that even an ex-Presidential should consider the dignity of the office he has filled, and if he enters journalism or business, any reference to the presidency is unsavory. We are among those who regret the needless notoriety won by Mr. Roosevelt by his magazine writings, the quality of which is not such as to do him particular credit. His 'Alone in Cuba,' as Mr. Dooley called it, was so absurd as to have killed any but the big man he is, and his hunting stories detract from his standing as a statesman. They are not particularly good, although the man, the reformer, and the president named Theodore Roosevelt is—and, we hope, will long continue to be—a tremendous force for righteousness in the national life of America.
BY THE WAY.

H. P. Breitenbach, writing to The Engineering Digest, says, the movement toward appreciation of the value of English as a college study is no doubt due to a more fundamental conception of the nature of the subject. It has been too commonly assumed that the ideal of language is correct grammar; or that its main element is the study of "figures of speech and other ornaments of style." At the bottom of these notions, and possibly responsible for them, is the shallow theory that makes rhetoric a matter merely of form, with no concern for, nor relation to, the content or meaning. Corresponding to this attitude toward rhetoric is the equally shallow view of literature as designed for mere amusement or pastime. The broader and deeper conception of language and literature relates them intimately with mind and with life itself. It accords with the established doctrine that thought and language are inseparable. The teacher of rhetoric and composition, accordingly, is no longer satisfied with an essay whose merit consists in correct spelling, punctuation, and grammar. He recognizes that, while these things have their importance, it resides not in themselves, but in what they represent. The teacher goes back of the words to the ideas for which they are symbols. His task, as he conceives it, is not to teach the student to put words and sentences together like building-blocks, but rather to train his powers of observation and analysis and so to develop and organize his powers of thought that clear and accurate expression will be the natural accompaniment. The corresponding view of literature regards it as a representation of life; its study is the endeavor to interpret the experience of others in terms of one's own experience.

Considered in this light, the study of his language and its literature, it is readily seen, will form an increasingly large part of the education of every successful professional man. With the maturing of his powers he will draw more and more upon the stores of knowledge which the race has accumulated in the form of literature; and correspondingly, too, he will extend his own range of influence through the expression of his ideas. For the engineer, the two main media of expression are drawing and the spoken or written word. As he advances in his profession, the latter becomes more important.

The influence of his speech on the success of the engineer is too often lost sight of. By the instructions he gives to his subordinates, by his conversations and discussions with his fellow engineers, and by his attitude toward those that seek his advice, especially when he has to address himself to an audience of some size, such as a board of directors, a learned society, or a meeting of the general public—by such means and in such cases his professional reputation and success are increased or diminished. When he appears in court as witness, says one of the chief authorities of the country on the legal aspect of engineering, he is apt to be unsuccessful "because of a lack of prompt comprehension of the English language." The ability of an engi-
Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

James W. Neil is at Butte.
J. H. Curie is in West Africa.
Harry J. Arkell is in Nicaragua.
William A. Farish is in Sinaloa.
Frank Probst is at Rawhide, Nevada.
W. B. McKinnell is at Durango, Mexico.
William S. Morse is here from Salt Lake.
Courtsey de Kahl has returned from Utah.
F. J. Booth is now at Cullaran, in Sinaloa, Mexico.
F. W. Oldfield, of Los Angeles, has come to New York.
Benj. F. Tibby has an office at Salt Lake City, Utah.
W. B. Winston has returned from a trip to Chihuahua, Mexico.

Jules R. Breckhaupt is at Santa Rosa, in Guadalajara, Mexico.
C. B. Hoadley is engaged in cyanidation at Searchlight, Nevada.
Herbert W. Ross is with the Cetro de Pascio Mining Co., in Peru.
C. V. Bird is manager for the Mond Nickel Co., in Ontario, Canada.

Eugene Barlow is at Salt Lake, and probably will proceed to New York.

S. D. Bridge, of Bridge & Tuttle, Monterrey, was recently in Durango, Mexico.

Godfrey Doyton is now associated with the firm of Spurr & Cox, at Mexico City.

Joseph E. White is superintendent of the Quartzite mine, at Searchlight, Nevada.

W. J. Barnett, who was recently in Siberia, is on his way from London to Nevada.

R. S. Rainford is manager of the Argonaut mine, in Amador county, California.

E. Seaborn Marks is in San Francisco, on his way from London to the Malin Peninsula.

S. Spence has been appointed business manager for Beck, Moreing & Co., in Butte.

Richard A. Paken has just returned from an inspection of iron deposits in southern Utah.

Jonathan P. Smith has returned from the Copper River country, Alaska, and he is now at Pasoadena.

Alex F. Reid has resigned as metallurgist to the Montana Mining Co. and is now at Los Angeles.

F. G. T. Nicholas has resigned his position as business manager for Beck, Moreing & Co., at Kaloochie.

Corey C. Brayton is superintendent of the Assentos plant of the American Smelting & Refining Co. in Mexico.

C. W. Geddes has completed an examination of the Sudbury nickel mines, in Canada, and is now at New York.

H. H. White suffered from a severe attack of pernicious poisoning while at New York. He is expected in California.

S. F. Shaw, of Pasoadena, has returned from Bodie, Cal., and is now examining copper properties in Sonora, Mexico.

W. J. Auw and F. Oratz Clarkie have opened an office at Velardea, Durango, Mexico, to engage in assaying and engineering.

Arthur L. Pierce, of London, and Philip C. Stross, of Seattle, have been in San Francisco, in connection with the business of the Alaska-Perseverance mine.

Arthur Thomas, who has been manager of the Pamatina mine, Argentina, for the last three years, has had to resign his position, owing to his health being adversely affected by the high altitude.

E. N. Skinner, who has been working for some years for the Guggenheim as assistant to A. Chester Beatty, is now connected with the mining department of Tripp & Co., 25 Broad street, New York.

Arthur W. Stevens, who has been in active charge of the Boise King placer in Idaho for the past two years, resigned in June so as to have time in which to make examinations in the northern part of Idaho. He has recently been appointed engineer for the Boise King Placers Company.

On Saturday, November 21, the first meeting of the Pacific Coast section of the Mining and Metallurgical Society of America was held at the Hotel St. Francis, San Francisco. Those present were: George W. Starr, Ernest A. Horsman, Mark R. Reer, C. C. Derby, F. W. Bradley, J. Nelson Nevius, H. W. Turner, S. B. Christy, E. P. Kennedy, Charles Butters, T. A. Rickard. The last mentioned was unanimously elected permanent secretary of the Section. The next meeting will be held on December 19, at the same place. A dinner at 6:30 p.m. will precede the discussion. Members of the Society, as well as those properly endorsed for election, are invited to notify the local secretary as soon as they are able to decide whether they will present at the meeting. The subject for discussion is that chosen by the Council, namely: What action may be taken by the Society to secure the publication of reports by mining companies which shall contain the information necessary for the full protection of the interests of mine investors? The next question to come before the Pacific Coast Section is the relation of the engineer to finance, lately ventilated in another place.

Silver per oz.
General Mining News.

ALASKA

(Special Correspondence).—Hot Springs, in the Rampart region of Alaska, aside from being the garden spot of the North, is backed by a most promising mining district, namely, Sullivan Creek, 15 miles distant. Sullivan Creek is the most accessible of the new camps, as the Government mail-trail crosses the Discovery claim. This camp is less than a year and a half old, and at the time of writing there are 300 miners on the ground; 20 laymen are on good pay and a big output is looked for this winter. There are both summer and winter diggings here. The Dakota group, of eight claims, is the best to date. Pans run anywhere from 50c. to $7.50. It is situated on the left limit of Sullivan creek, and has an average depth of 60 ft. On Discovery claim, which is on the right limit, and from which $20,000 was taken in two months, the gravel is but 30 ft. deep and pay is found at 20 ft. The camp, which gets its name from M. J. Fletcher, one of the firstlocators, received no attention until three prospectors by the name of Kemper, Snyder, and Harter made their find on Discovery. Association claims, the curse to the diligent and well-meaning prospector, have been the means of keeping luck away from the camp, and while our mining laws permit and make it possible for a few men to stake a country from Dan to Beersheba, there will ever be trouble. The cry from Swann and in every mining camp, where the prospector may stand a reasonable show is: "Abolish the association claim!" However, things are righting themselves, and much litigation has been avoided by the coming at the nick of time of mining operators with capital, who have purchased the controlling interests in two associations that have made good. On the Dakota group, the following laymen will operate this winter: John Swann, junior. The last of August will be worked by: Neville, Eraths, and Lowe, 12-hp. boiler; while Fitzgerald, Jones, and Davenport, Lyn Smith, and Sam Oaktler are also expecting large plants to operate their lays, and E. Richards, of Fairbanks, a well-known mining operator, will install a 30-hp. plant on a 250-ft. lay. The other claims on the left limit which have shown pay and which are lined up will be worked by: Leonard Dodge with 16-hp. boiler. The Abe Lincoln will be worked on a large scale by Gill Edgar. So much for Sullivan creek. As to its numerous tributaries, I shall mention a few that have shown pay: on Quarts creek, a tributary on the left limit, Johnson & McIntyre have had a crew working all summer in good dirt, and have found the pay six feet from the surface and good prospects from the moss roots down. Tufty gulch, the banner tributary of Sullivan and the creek that has produced the most to date, is on the right limit opposite Discovery. Joe Egler, the well-known mining operator of Esther creek and Fairbanks, has purchased the controlling interests in Tufty gulch, and a 60-hp. plant is expected for this creek. Woodchopper creek, which empties into Sullivan five miles below Discovery, also shows ground that will pay to work. Booker, Krouch, and others, with a large outfit, will work there this winter. The miners in general are well pleased with the road work that has been done this summer, and much praise is due to the Road Commission for their timely services. The N. C. Co. has now taken over the trading post of F. G. Manley, and the Manley hotel has been crowded all fall. Hot Springs will soon have another newspaper. Word and Arbourcle being the proprietors. Hot Springs, November 12.

CALIFORNIA

PLACER COUNTY.

Nearly a mile of track has been laid in the old Panzgo adit. Gravel is being taken out and the mill is run one shift per day. The removal of a blockade in the lower adit and the consequent rush of water and dirt into Volcano canyon, buried the flumes and boxes of West & Co. and stopped work for a time. —Ed. Kavanaugh has a small force of men at work at the Black Canyon quartz mine. —W. S. Fletcher has a small force working the back tunnel of the Dardanel. The breast in the gravel is 8 ft. high and is gradually increasing. The normal depth is 14 ft. The gravel is rich, running from $5 to $20 per pan.

SHASTA COUNTY.

The Fairview mine, near Minersville, which is operating 15 stamps, has a force of from 30 to 40 men employed. The clean-up is averaging about $10,000 per month. —The Mammoth Copper Mining Co. is putting in a new powder-throwing plant near the present magazine, to have a capacity of about 24 hours' powder supply. An electric heater will be used. —The Dorleska mine, near the head of Coffee creek, is under lease to M. H. MacIlwaine, C. E. White, John and Charles Kingsbury. Good ore has been taken out and a mill run will be made this fall. Mining operations will be continued all winter for an early spring run at the mill. As the lease will expire early next year, work will be pushed.

SISKIYOU COUNTY.

Assessment work is in progress at the Pacific, at Howland Flat, and it is probable that eight or nine men will be employed all winter. —William Casterly is foreman. —A force of men are working at William Shaughnessy's saw-mill at China Flat getting out the timbers and lumber necessary for the building of the Gray Eagle tramway. A cable and accessories have been delivered on the ground, and if the weather continues good for a few weeks the tramway will be in running order. —M. R. Rose, of Goldfield, has taken a bond on the Eureka quartz claim, near Forest, and will start development at once. Perry Bixby is the owner. —Charles Delamare Maze, of San Francisco, has purchased the sulphurates of the Empire mine in Gold valley and will work them himself this winter. He will use the old mill and expects to employ two or three men. —J. C. Chandler has returned to Forest and will at once start work again on the shaft he is sinking on the site of the old Forest House. He intends to go down to a depth of 500 ft. and has all his timbers out and ready to haul to the ground. A gasoline engine is in Nevada City and will be hauled to the ground immediately.

SOLANO COUNTY.

The Cook & Green group of copper claims, near the Blue Ledge camp, has been sold to W. A. Phillips, of London, England, who is said to be organizing a company to work the property.

TOLUOLUMNE COUNTY.

Lack of water to supply power has forced a suspension of operations at the Jackson mine at Toulumne. —A gasoline engine and hoist have been put in at the Sweeney. —Jesse Burns and William Hampton have bought a half interest in the Lodl, and will proceed to extend the adit to tap the vein in the shaft at the depth of 60 feet.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Work was again started this week in an attempt to make connection with the Seven Thirty shaft from the raise made from the West Phillips drift, of the Burleigh adit. Owing to the great danger to life and property, Owen Rice, who is manager, has secured a diamond-drill and the ground is to be prospected in a thorough manner. Surveys show that the raise is 36 ft. above the bottom of the shaft, but as the old maps have either been lost or destroyed, it is impossible to tell the exact location. With this piece of mining completed, one of the early-day heavy producers of silver-lead ore will have been rejuvenated. —Work is to be carried on throughout the winter months on the holdings of the Ruby Argen- tine M. & M. Co. Supplies have been taken in and a force of 10 men will continue work in mining the Calla adit. A vein was intersected last week, but only small streaks of ore are showing. No driving is to be done until the head
ing of the bore cuts the Calia vein, which is supposed to be between 50 and 70 ft. distant. R. C. Vidler, of Golden, manager.—H. M. Vincent, owner of the Revelle group of claims, is employing a small force of men in driving his adit. The bore is in 900 ft., three veins having been intersected. No driving has yet been started.—The Vesper group of claims is making a fine showing. Since the Gold Coin vein was cut, driving has been started and a small streak of ore is showing that is worth $275 per ton in gold and silver. G. Crump is manager.—A 6-m. streak of silver and ore has been discovered 1660 ft. from the mouth of the lower adit of the Wide West mine. Driving has been started. L. Bachelier is lessee.—M. Jacobs has put men to work on the Old Hickory group of claims, on Columbid Mtn. The adit is to be advanced for the intersecting of the series of veins controlled.—J. G. Hite is at work in the development of the White vein. The adit has been driven 150 ft. The crevice is five feet wide and the vein runs as straight as a die. A big body of quartz is showing, while occasional feeders of exceptional high-grade ore put in their appearance.—The Conqueror G. M. Co. is employing a big force of men in the development of its holdings on Covode Mtn. Drilling is in progress upon the Conqueror vein and a body of ore is exposed that is from three to four feet wide. The mill is being remodelled and will hereafter be ready for ore. It is expected to be in operation and bringing ore within 30 days.—The Knickerbocker M. & M. Co., recently organized, has started a force of men at work in the development of its holdings. A plant of machinery has been ordered, which it is expected will arrive within the next 10 days. Operations for the present will be confined to surface, but later on arrangements will be made whereby work will be carried on through the Emperor adit. Construction of a modern concentrating plant is being considered. William E. Hogel, of Idaho Springs, is manager.—The Equity Con. M. Co. has been incorporated with a capital stock of $1,100,000, to develop a group of claims on the line of the Newhouse adit. R. J. Bardwell, of Denver, is resident agent.—During the last month 15 leases have been granted by W. S. Leebrock, of Idaho Springs, manager of the Littie Matie mine, on Chicago Mtn. Work is well under way and heavy shipments are promised for the future.—The Crazy Girl is to be started by John Cousins. The adit will be driven ahead to cut under the shaft workings, from which high-grade ore was mined a few years ago. The property is situated up South gulch in the Fredland district.—From 1200 to 1300 tons of 3 to 5 oz. gold ore are being shipped from the South Pacific mine, Seaton Mtn. Operations are conducted through the Two Brothers adit.—The Salisbury mill is running night and day upon ores from the Stanley mine. Only material of a low grade is being treated, but the finished product is worth from $35 to $40 per ton.—The Burns Moore adit has now been advanced for 3243 ft. A few days ago the Parnell vein was intersected, and while ore in paying quantities was not found, the entire vein matter is heavily mineralized. In a vertical line the Parnell apex is 825 ft. above the adit level, and it became necessary to drive 1210 ft. beyond the apex before the vein was reached. This gives about 1350 ft. of vein on the dip. W. W. Cannady, of Idaho Springs, is manager.—An 8-in. streak of $100 ore has been uncovered on the Amazon, Seaton Mtn. This property is being operated by a group of local men, headed by James Humphrey, of Idaho Springs.

Georgetown, November 21.

EAGLE COUNTY.

The Colorado Fuel & Iron Co. is operating the Black Iron property near Red Cliff, producing nearly 4000 tons of manganes ore per month, which goes to their steel plant at Pueblo. This is the biggest production the Black Iron has experienced for several years, and has aided in booming the Eagle county district.—Arrangements are being made for the erection of a large mill on the Iron Mask property. Ground is now being broken and material is on the way. Al Pascho, formerly of Leadville, is in charge of the work. The plant will treat the zinc ore produced at the Iron Mask mine, and will also make a bid for the treatment of ore produced at other small properties in the same neighborhood.

TELLER COUNTY.

A strike of unusual character is reported from the Durango Gold Mining Co.'s No. 2 shaft, operated under lease to the British-American Mining Co. The find has been made in the slope between the 400 and 500 ft. levels, where machine-drills are in operation in the development of a six-foot vein.

McConnell and associates, residents of Cameron, have secured a prospecting permit with an option to lease Block 8 of the Bonanza Contact Mining Co.'s estate on the northwest slope of the Frontal hill, and have commenced work at surface. This leasing block is situated in the precasted area near the main shaft. Work has been resumed by Fred Baker and associates, holding the lease on the Mountain Goat and other holdings of the Comanche Plume Mining Co. on the western slope of Battle mountain.

GILPIN COUNTY.

Knudson & Son, of Philadelphia, have taken a lease and bond on the Leontine claim on Quartz hill, near the Ivanhoe property, and have been cleaning out the shaft and doing some re-timbering work preliminary to carrying out active developments. The shaft is reopened and is expected to be in operation and bringing ore within 30 and 90 ft. deep and the lessees will probably sink so as to open up some new ground.—Harry Arnfield & Co., of Nevadaville, have taken a lease on the Forks mine on Quartz hill and have commenced preliminary work.—It is reported that as soon as the Searie mine in Willis gulch is connected with the main line of the Gilpin tramway a compressor and hoisting plant will be installed. The property is owned by the Druil Mining Co., for which Joel F. Valle, of Denver, is superintendent and C. W. Anderson is manager.—Articles of incorporation of the Rio Claro M. & M. Co. have been filed with the county clerk and recorder showing capital stock of $350,000, and with Henry A. Hicks, Richard H. Brown, and Edward W. Davis as incorporators. The company will operate in Gilpin county and will have its main office in Central City.—W. J. McFarland, of Toledoo, O., is at Central City, to look after interests in the Parole and Morning Star claims on Bobtail hill. He will at once make arrangements for the installation of a first-class plant of machinery and for the erection of a shaft building, expecting to commence active developments before the close of the year.

LAKE COUNTY.

F. E. Hayden has leased and bonded the Dolomite, Laurel, and Echo claims to S. P. Panton, of Buena Vista, work to begin not later than December 1. These claims are in Adelaide Park, and their surroundings, as well as actual discoveries make the ground extremely promising.—Timothy Kyle has a small force of men at work on the Boulder property in Biz Evans gulch. It is likely that this shaft will be worked during the winter. The entrance of the Yak tunnel into that section has drained the property, which will allow its thorough exploration. The Boulder has not produced for several years, but has been handicapped by water. With this difficulty eliminated, it is believed the mine can be placed on a paying basis.—Simon Wheatley has a force of men at work driving the Rosse adit on a contract with the Independent District Consolidated Mines Co., which was recently incorporated to work the Berdella and St. Kevin properties west of the river. In addition to running 200 ft. on this work, he will also clean out the old adit which was driven in the early days. As soon as the Wheatley contract is completed, another of 200 ft. will be let. Under this system the entire distance of 1200 ft. to the old St. Kevin and Grand View veins will be driven. In the meantime work is going on at the Berdella to effect management of the Company. The bore is now 325 ft. Arrangements are now being made to install a steam-power plant at the Berdella. Eventually electricity will be used.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The principal feature of the mining industry of the Coeur d’Alene during the past week
has been the general stand taken by the district in connection with the tariff on lead and zinc ores. Toward the beginning of the week word was received to the effect that the tariff on lead and zinc ores would be brought before the Congressional committee, dealing with the tariff revision, about November 25. Accompanying this report came the rumor to the effect that an organized attempt would be made on the part of certain smelters and manufacturers to have this tariff reduced. Without an instant's loss of time mass-meetings of the people of the district were called in every town of the Coeur d'Alene. At each of these meetings ways and means of combating any reduction of the tariff were discussed and two delegates were elected to a second meeting of the business men and mine operators held in Wallace Monday. In the meantime petitions against the reduction were drawn up and circulated, receiving the signatures of practically every man in the district, communication was entered into at once with Senators W. D. Heyburn and William E. Borah, of this State. At the meeting of the delegates and operators, in Wallace, the following committee was selected to go to Washington to appear before the Congressional committee and when the matter of ores should come up for discussion: W. Clayton Miller, William J. Brand, Herman J. Reiss, Al Page, and D. E. Keys. All of these men left Wallace Wednesday and the expenses of the delegation to Washington will be met by the operators of the district. —H. F. Samuels, the owner of the Success mine and the man who first solved the problem of extracting zinc from the ores of this district, has returned from a trip to British Columbia, where he inspected the new electric zinc smelter recently erected under the auspices of the British Government to operate the patents of Snyder and others. Mr. Samuels expresses himself as delighted with the trial, and has made the announcement that if a continuous run of the plant proves equal to the trials which he witnessed, he will erect a zinc smelter in Wallace to the detriment of the owners of the Success mine and other zinc properties of the district. —A contract for 100 ft. of work has just been let on the property of the Snow Cliff Mining Co., in the Lookout district. This property is practically an undeveloped prospect, but several rich strikes in the adjacent mines have caused the owners to accept and offer on a pure stock basis. —A new company, known as the Idaho-Knickerbocker Mines Co., has been formed by A. J. Stack, to exploit the property of taking and running the property of the Charles Dickens Co. over which there has been so much ill feeling and litigation recently. The new company has a capitalization of $1,500,000 in shares of a par value of $1, and Mr. Gritman has subscribed to the whole, with the exception of 50 shares. Holders of stock in the old Charles Dickens company are offered an amount of stock in the new company equal to their old holdings in consideration of permission to develop wherein they have been interested. —A large amount of development has been done and the company is planning to build a mill. The Mason mine is to be started under the new management. A water-tight pump has been installed. The 2 F mine is being put in condition to operate again. This is the only day light mine in the camp and tons of the ore can be seen from the surface. One of the best galena strikes in the camp was made by Creech & Co. in the Joanna mine. Large chunks of free galena were found both in the north end and in the southeast part of the lease. A car of chunk lead will be shipped from mine. —A contract for the lead mill is progressing rapidly and a large amount of development work has been done to insure steady production when the mill is finished. —One of the most important strikes in this portion of the camp was made at Keevile on the Ludlow farm, west of Baxter Springs. The ore was struck in a drill-hole at 160 ft. and a 10-ft. face was opened up. More drilling will be done. The vein is important and is coming up, as it is in virgin territory, the first in that region. Adjoining leases have been taken rapidly and will be prospected. Galena, November 20.

MISSOURI.

JASPER COUNTY.

(Special Correspondence.) —The past two weeks has noted some exceptional strikes all over the county. On the Whitworth land, north of Web City, the richest sheet-ore strike of that portion of the camp has been made. In 11 drill-holes the ore was struck at 150 ft., showing a 14-ft. face of zinc-blende and galena. Two holes were sunk below this run and 18 ft. struck a second run fully as rich, but with a 19-ft. face of the ore. A shaft has been started and development work will be hastened. —A rich face of zinc-

plastering dust over the entire face of the drift. This ore be claims to have uncovered by the use of a pick. Samples of ore are taken and sent to several different places, where they all showed chalcopyrite and peacock copper assaying all the way from 3 to 36%. Mr. Eddy states that the vein runs all the way from 5 to 35 ft. wide and several hundred feet long. An assessment of two cents per share was recently made on the capital stock of the Company and the payments are said to be coming in satisfactorily. It is expected that a resumption of work will be made in the near future.

Wallace, November 21.

KANSAS.

CHEYENNE COUNTY.

(Special Correspondence.) —McKinney & Co. have finished the new shaft near the mill and have found good zinc-blende at 124 ft. The ore is high-grade and is found in large quantities. A tramway has been completed to the mill.

Operations are to be resumed at the Hartford mine, in the Empire district. The 250-ton mill is practically new, as it was completed last spring and operated only a short time before the company closed down. A pump has been installed at the shallow drifts to drain the ground and larger pumps will be put in for the lower levels. The mill shaft is 172 ft. deep and a drift has been started to another shaft 300 ft. distant. When it is completed ore will be hoisted from both shafts. —The 200-ton mining plant of A. G. James, in the Cave Springs district, has been overhauled and will be started at once. The ore on this tract is found from 110 to 160 ft. and the land is well developed. A peculiar feature is that the ore is found at the lowest level and is of unusual richness, while the zinc-blende is above the galena deposit. The opposite conditions usually prevail in the Joplin district. —The Black Jack property, in Baxter Springs, was the scene of a good strike last week. No. 2 shaft was being sunk when at 85 ft. the cap rock was penetrated and the ores, both galena and zinc-blende, were found in open ground. The company has started shaft No. 5 at a point where the deepest deposit is at 114 ft. A contract will be let for a large mill to be erected this winter. —A number of properties are to be started in the Baxter Springs camp soon. The Hannibal & St. Joe mine has been drained preparatory for resumption. The Alabama mill has just been started. A large amount of development has been done and the company is planning to build a mill. The Mason mine is to be started under the new management. A water-tight pump has been installed. The 2 F mine is being put in condition to operate again. This is the only daylight mine in the camp and tons of the ore can be seen from the surface. One of the best galena strikes in the camp was made by Creech & Co. in the Joanna mine. Large chunks of free galena were found both in the north end and in the southeast part of the lease. A car of chunk lead will be shipped from mine. —Work on the Lucile mill is progressing rapidly and a large amount of development work has been done to insure steady production when the mill is finished. —One of the most important strikes in this portion of the camp was made at Keevile on the Ludlow farm, west of Baxter Springs. The ore was struck in a drill-hole at 160 ft. and a 10-ft. face was opened up. More drilling will be done. The vein is important and is coming up, as it is in virgin territory, the first in that region. Adjoining leases have been taken rapidly and will be prospected.
November 28, 1908.

MINING AND SCIENTIFIC PRESS

blende has been opened up at 35 ft. on the Cox land on Turkey creek. The ore mills 29½ on a custom plant.—

The richest strike ever reported from Reeds station was recently made by the Grace-Clark Mining Co. The Company has been operating about three weeks and in that time has taken out 19,000 lb. of silicate and 5000 lb. of zinc-blende. Some chunks of the silicate weighing 200 lb. have been hoisted from a depth of 60 ft. Ore is found in this vicinity at both shallow and deep levels. Many small silicate diggings are active, while the Ravenwood Co. is operating sheet ground from 200 ft. to 250 ft., loading a car of zinc ore per week.—Two rich strikes have been reported from Car Junction within the week. Smith & Brunmit, operating a lease of the Smith-Moler land, have struck ore at 47 ft. which runs 30%. The ore will be cleaned on hand-jigs, as it is rich and free from iron. New machinery is being installed. The second strike was made by the Jubilee Mining Co. at 75 ft., with the ore extending to 95 ft. The ore was first cut at a shallow level, but the richest was found at 75 ft. Development has started and hand-jigs are being installed to treat the ore. Among the new mills of the district one of the largest is the Marvel mill, on the Cosgrove land at Duenga. The plant is only just com-

A Joplin Mill.

pleted and has made one turn-in. The Cosgrove land is among the richest of the sheet-ore properties in the district, the ore running from 10 to 25% zinc-blende and 2 to 3% lead. The mill is owned by Bruhaker Bros., who are operating the lease.—A small mining plant is being in-

stalled at the Thirty Year Mining Co.'s land in West Hol-

low. A rich body of galena and zinc-blende has been re-

cently developed there. The Navy Bean mill at Went-

worth has been dismantled and is being moved to the Honk lease, on Turkey creek. The mill will be a plant of 150 tons. The ore at the old Navy Bean mine, at Wentworth, will be handled by a mill in the vicinity. The old Honk property was operated years ago, but was abandoned on account of water. The new centrifugal pumps have drained the drifts without difficulty and the old workings are being rapidly re-opened. Number of properties are resuming operations after shut-downs for various reasons. The old Hag-

gertt mill, southwest of Joplin, has been overhauled and new machinery added. This was the first plant to be built in that portion of the camp and has done much for the original development of the rich southwestern field in the Joplin district. The White Dog mine in the north Webb City field has been started again and is one of the best producers of sheet-ore in the district. The ore is taken from the 165-ft. level. The new mill has a capacity of 250 tons.—One-half of the Monark-Nemo mill north of Webb City has been started. The double plant has a capacity of 800 tons. It was built to handle the ore from two leases from 28 to 50 ft. and a deeper and richer run from 60 to 80 ft. Hand-jigs are used and the equipment is to be doubled.—West of Webb City the Whitworth land is being developed by R. B. Tyler for coal, lead, and zinc. At present the coal is being mined where veins from 5 to 10 ft. deep are found. The coal is good grade and finds a ready market at the mine. Later the ores of galena and zinc-blende will be developed at the lower levels. West of Carthage the Tri-City Mining Co. has at last begun produc-

tion. The phenomenal drill records of last winter at-

tracted the attention of the entire district and its de-

dvelopment has been watched. The shaft is now down 187 ft. and the ore is at the present being treated on hand-jigs. A mill is planned for the early spring.

Joplin, November 30.

LAWRENCE COUNTY.

(Special Correspondence).—General activity increases in the Aurora camp at the extreme eastern end of the district. Stripes have been made recently on the Spalzertle, the Boston-Aurora, Cleveland-Aurora, and Big Bonanza tracts. A large part of the turn-ins comes from the shallow mines. About 16 new shafts are being sunk. The United Zinc Co. has started the pumps at its No. 6 and 8 shafts and will commence work when the ground is drained. The mill on the property has been closed down for ten months, but weekly turn-ins have been made by the sub-leases on the shallow ground. Practically all the properties in the Sarcoxie camp are active. A shaft is down 200 ft. on the
J. W. Boyd land, west of town, and driving has been started at 160 ft. A concentrating plant will be erected. The ore in this camp occurs from 16 to 160 ft., the shallower runs being mainly silicate, while the deeper deposits are very rich zinc-blende. At a depth of 14 ft., a rich vein of silicate was discovered on the Murray Cale land west of town. The contract has been let for the erection of a mill on the Cameron lease on the Boyd land. The company has been engaged in developing the tract for the past three years. A large shaft is sunk and the ground thoroughly tested in every direction. The ore is high-grade zinc-blende. Aurora, November 20.

WASHINGTON.

STEVEN'S COUNTY.

(Special Correspondence.)—At the Butte & Washington mine, near Hall's bridge, east of Kettle river, Fleetwood Ward has let a new contract to drive an adit, which is calculated to tap the vein at 1800 ft. from the portal. It is now in 500 ft. Gold, silver, lead, and copper are found on the surface. Recently a large body of lead carbonate ore on the summit of the hill was stripped and found to be high-grade.—The First Thought Gold Mines, Ltd., has completed the foundations and is now installing a 60-hp. gasoline engine, a five-drill air-compressor and other machinery and will use machine-drills in the First Thought mine in future. The Beeches camp, Ltd., has completed a two-mile wagon-road, with easy grade, from its new camp at Rockcut, on the Spokane Falls & Northern railway. The manager says that the Company will purchase machinery and install a mill as soon as possible. Timber is available on the ground and also water-rights for milling and camp purposes. The first carload of free-milling gold quartz was shipped to the Northport smelter two weeks ago and is reported to have been very rich. While at Orient, W. C. Cameron saw some beautiful specimen quartz from the mine, equal to anything of the kind he ever saw in California. The board of directors has decided to drive an adit 225 ft. to intersect the vein at the shaft, at a depth of 115 ft.; also to install a stamp-mill, compressor plant, and a gasoline engine suitable to drive them; also to lay water-pipe for milling and camp purposes as soon as possible.—The McKinley group, in Pierre Lake district, has been visited by the president of the company, C. F. Wicksstrom, of Spokane. He said a hoist and pumping plant will be installed at once, and more machinery added later. The McKinley group consists of 8 claims, two miles north of the Beecher mine. A shaft has been sunk on a narrow vein which is 26 in. wide at a depth of 22 ft. Other veins outcropping on the group are developed only by open-pit mining.—A new wagon-road is being built from this property down Deep creek, to a point opposite Laurier, a station on the Spokane Falls & Northern railway.—Work has been resumed in the Little Giant mine.—A 75-ft. contract has been let to extend the adit on the Globe mine. Two shifts will be employed.—A mine-car, track, and other equipment have been ordered for the Valley Dew mine.—The management of the Bryan and Silver Cloud groups, near Rockcut, is contemplating the installation of a compressor plant, hoist, and other equipment. W. A. Graves and H. G. Malette, of Rockcut, are the principal owners. Culville, November 21.

MEXICO.

JALISCO.

(Special Correspondence.)—The famous Cinco Minas, in the Hostotipaquillo district of Jalisco, are under option to the Marcus Daly estate of Butte, Montana, and New York for $25,000. The purchase is regarded as certain, and it is believed that the deal will be closed within 90 days. Henry E. Crawford, of New York, is representing the Daly estate in the negotiations. The Cinco Minas are antiguan, their development dating back to Spanish colonial days. Several big bonanzas have been found, but while practically all the rich ore has been taken out of the old workings, there is a big supply of milling ore in sight, and it is felt that the new development work may uncover other bonanzas. If the deal for the mines is closed a modern reduction plant will be erected by the Daly interests.—Col. Epes Randolph, head of the Harriman interests in Arizona and Mexico, is one of the men principally interested in the Cinco Minas. The Central mines at Tepic are also involved. The deal was made recently by M. P. Wright, of Los Angeles, acting with Sidney D. Kempson, who held on option for the purchase of the properties. The price named is $50,000. The mines have been owned for a number of years by Lonergan & Stanhope, an English firm that has been identified with Tepic for a quarter of a century. The plans of the new owners include the installation of a hydro-electric plant and the equipment of the properties with modern reduction facilities.—The Manzano extension of the Mexican Central railway has been accepted by Eduardo Prieto Benuz, representing the Federal Government, and a mixed train is now in operation between Tuxpan and Colima. The new Mexican Central time-card will go into effect December 1, and on that date the extension will be opened through to Manzano. President Diaz has accepted the invitation of the Mexican Central officials to participate in the formal inauguration. The new capitalist of San Antonio, Texas, is closing a deal for the San Jose, Deseda, and Espada mines in the Hostotipaquillo district of Jalisco for approximately $150,000. The Deseda and Espada are extensions of the famous Cabrera vein of the Hostotipaquillo district, and are owned by Carlos Romero, of Etzatán. The owners of the San José are Sr. Romero, Alfred Lundrall, and the San Antonio Mining & Milling Co. No details of the transaction are available, but it is expected that Mr. Wick will personally provide funds for the further development of the properties and the erection of a reduction plant. Edward Thomson, a California mining engineer, is representing the San Antonio men.—Manuel Cuesta Gallardo, of Guadalajara, announces that he is ready to enter into contracts for the transmission of electric power to mines and mills in the Etzatán and Hostotipaquillo districts on and after July 1, 1908. The Amparo Mining Co., operating in the Etzatán district, has already contracted with him for 700 hp. Sr. Cuesta Gallardo is the man who has a Federal concession for the utilization of the water of Lake Chapala for irrigation purposes; Federal concessions covering the water-power of the Santiago river for a number of miles; and a State concession for a competing light and water system in Guadalajara. He has entered into a contract with the Mexican Government to construct a system of electric power amounting in value to more than $7,000,000, and this contract is guaranteed by the Mexican Government. It is estimated that from 200,000 to 300,000 hectares (from 489,000 to 741,000 acres) can be irrigated with the water that is taken from Lake Chapala, and under the new irrigation law the concessionaire will receive a subsidy of $50 per hectare in addition to the charges collected from the owners. Some machinery is now on the way from Germany, and this will be installed at the site of the initial hydro-electric plant, about 20 miles from Guadalajara, where the necessary hydraulic works have been completed. The building of a transmission line to the Etzatán and Hostotipaquillo districts will be commenced early in the coming year. With the advent of electric power the Hostotipaquillo district is expected to become the scene of great mining activity. There are in that district great supplies of dump ore that can be profitably treated by modern methods, and the orebodies of the district are of unusual size. There is promise that it will develop into one of the most important milling districts of Mexico.—The Amparo Mining Co., of Philadelphia, is now crushing about 3700 tons of ore per month in its 40-stamp mill. The treatment is concentration and cyanidation, and extraction of from 90 to 92% is secured. It is estimated that the ore now in sight in the Amparo mines is sufficient to keep the reduction plant running at its present capacity for at least ten years. Guadalajara, November 18.

A South American gold dredging proposition that has given English shareholders plenty of anxiety is situated on the Kaka river, behind La Paz, Bolivia. The properties were sold by the local owners, the Kaka Mines Co., to an English company called the Incahuara Dredging Co., in the spring of last year. The management is in the hands of John Taylor & Sons, and the engineer on the spot is A. P. Stockings. The English company paid £60,000 in shares and £10,000 in cash to the vendors, and issued 35,884 shares of £1 each for cash, which was available for working capital. The directors have apparently not taken sufficient heed of the expert advice available in John Taylor & Sons' office. At any rate, they were unaware of the engineering difficulties that confront the pioneer in the high lands of Bolivia. They had been promised by the Bolivian government that a road would be completed as early date from La Paz to Caranavi, and from thence to Puerto Pando, between which two places the property is situated. The contract for the construction of this road had already been taken in hand by other parties. It was not long, however, before these people were glad to give up the contract and to hand it to the Incahuara company. Accordingly, the present company took the matter in hand and, aided partly by government grants, completed the road to Caranavi in February last. Then came the second difficulty: A dredge had been built by Lobnitz, of Scotland, and on general principles the component parts were made as small as possible, so as to facilitate transport in sections. But it was found that the dredge was even then far too heavy, and the engineer is now exercising his wits with the problem how to get the dredge to its destination. A good many of the parts cannot be split into smaller pieces, owing to the absence of sufficiently skilled labor to put them together again. So the pieces not suitable for mule transport have to be laboriously hauled up the road to Caranavi, and it is hoped that the rest of the journey can be effected on rafts. Unfortunately, the company has come to the end of its resources, and another £20,000 is required. The original vendors are very keen that the work should go forward and have voluntarily surrendered 20,000 of their shares, and the directors and shareholders in this country will probably take up these shares and so provide the necessary funds. I give this case as an instance of the fact that the engineering problems connected with dredging operations are but little understood in this country.

There is a strong probability that the Nobel explosives factory, in South Africa, will suspend operations before long, or at any rate the output will be considerably curtailed. The cause of this policy is the fact that the explosive factory owned by the De Beers interests has secured a nine years' contract for the supply of dynamite to the principal Rand groups. The Nobel factory is situated at Modderfontein, and is owned by a company called the British Explosives Co. The De Beers company is at Somerset West, in Cape Colony, and is owned by the Cape Explosives Works. In 1902 the leading mines on the Rand agreed to purchase one half of their explosives for a period of seven years from the De Beers factory. Now that the new contract provides for the whole of this business, instead of half, the factory at Modderfontein is hit hard.

Though many statements have appeared from time to time in the press relating to the final form to be assumed by the famous Cullinan diamond, nothing authentic has been published until this week. This diamond was found in the Premier mine, in the Transvaal, in January, 1905. Its weight was 5025 carats, and it measured 4 1/2 by 2 1/2 inches. The previous largest diamond known was the 'Excelsior', which was found at Jagersfontein and weighed 971 carats in the rough. After much speculation as to what to do with the stone, the Transvaal government, which has a 60% interest in the mine, decided to present it to King Edward VII, and it was accordingly handed to him as a birthday present on November 9, 1907. On January 23 of this year it was sent to Joseph Asscher & Co., of Amsterdam, for the purpose of cutting. This work has now been completed. The stone was of blue white color, of fine quality, but as there were certain flaws in it, considerable study was required in order to get the best results in cutting. Altogether nine stones of notable size have been obtained from it, together with 96 small brilliants, weighing in the aggregate 75 carats, and a quantity of unpolished bits weighing altogether 9 carats. The most important of the stones is a pendeloque or drop brilliant, weighing 516 1/2 carats and measuring 2.323 in. long and 1.791 in. wide. The second stone is a square brilliant weighing 309 1/2 carats, measuring 1.771 by 1.594 in. Even this second stone is far larger than any other cut diamond in existence, the largest hitherto being the 'Jubilee' diamond, weighing 225 carats, and still in the possession of the Diamond Syndicate. The next largest is a brilliant weighing 196 carats. The thing cut from the Cullinan is a pendeloque weighing 92 carats, and the fourth a square brilliant weighing 62 carats. The other five stones are of various shapes and weigh 18%, 11%, 8%, 6%, 5%, and 4 1/2 carats, respectively. All these stones are of the highest quality and are absolutely without flaw. An innovation has been made in cutting the two large ones: usually a brilliant has 53 facets; in the case of these two stones the number is 76 and 69 facets.

An interesting document has been issued by the Consolidated Goldfields of South Africa, relating to the company's holdings. As a rule a parent company of this nature does not find it advantageous to disclose its business, and the decision to adopt this policy has been accordingly received with special attention. But the curious part about this schedule is that it is incomplete, for, after enumerating 40 companies in which the Goldfields holds shares, the statement winds up thus: "in addition to the above, the company holds shares and debentures in various companies which on quotations of June 30 last, or estimated value, represent a further value of £235,900." It is thus disappointing not to be able to find out what the Goldfields has in the Dunderland Iron Ore Co., the Tywarnhaile Syndicate, or the Russian Goldfields Corporation, in which each of these companies has holdings, and which have been referred to recently in these columns. These companies do not appear among the forty, so are presumably lumped together with others. However, in spite of this cursory criticism, the list of specified investments is one of great interest. The largest interests are still in South Africa, and consist of large blocks of Simmer, City Deep, Knights Deep, Jupiter, Robinson Deep, Simmer Deep, Turf Mines, and others. The Simmer & Jack mine is a close rival with the Robinson (not the Robinson Deep, referred to above, but the Robinson of the Eckstein group) as the premier gold producer, both yielding about 25,000 oz. per month, and the Jupiter is of interest at present, as it has just started crushing. Among outside investments specified in the list there is included 24,012 shares of S£ each in the Vale Consolidated Goldfields; 13,999 shares of S£ each in United States Smelting, Refining & Mining Co.; 56,652 shares of £5 each in Grovelite Dredging; and 6,858 shares of £1 each in Spassky Copper (Russia). It is of interest to note that H. H. Webb, the company's consulting engineer, during his recent visit to America obtained a number of new investments for the company.

John Henry Holman died at Camborne on November 4. To Cornishmen the name of Holman is a household word. The deceased's grandfather Nicholas was associated with Richard Trevithick. His father founded the engineering works now owned by Holman Brothers, Ltd. He and his brother, James M. Holman, for many years carried on this business, which under their direction increased rapidly. He also had many interests in Cornish and other mines,
and he was a public-spirited man in connection with municipal work and the affairs of the church. He was stricken with illness three years ago and never recovered. He had just completed 55 years.

MEXICO.

At last the country west of Guadalajara, particularly around Amea and Etzatlan, in the State of Jalisco, seems to be obtaining the share of attention it deserves. For several years the only really large operators in all that district were the MacKeever Bros., working the El Favor in Hostotipaquillo, north of Etzatlan, and the Amparo Mining Co., working the Santo Domingo mines, just south of Etzatlan. The latter for a long time has been a large producer, and for over a year has had its 100-ton cyanide mill in successful operation, while the MacKeever have given their entire attention to El Favor for over two years in development work and the testing of the ores, until about a month ago, when an order was placed with Chalmers & Williams for the first unit of ten 1000-hp. stamps, Willey tables, and free vanners, with tube-mills and cyanide vats, all of which should be delivered early in January, 1909. With the exception of a few American companies, such as the Casados Mining Co. and the Virginia-Mexico Co., the other operators have been Mexican, of which the more important are the San Pedro Amado Mining Co., of Guadalajara, and Molonos, of Carlos Romero, Etzatlan, both really important producers that may be considered as being in Hostotipaquillo, although San Pedro Analco lies considerably to the northeast and Molonos to the northwest of Hostotipaquillo. But now that the Marcus Daly estate has entered the Etzatlan district by purchasing the Cinco Minas, just east of Hostotipaquillo, for $100,000, and Daly's former associate, Patrick Clark, has taken over the Magistral, near Etzatlan, it is certain to attract outside capital to this region. This must result in great good during the coming year, for there are many properties between Guadalajara and the coast that simply need the capital to make of them excellent producers, and the rapid extension of the railroads from Guadalajara and the leadership of Daly and Clark are going to prove the incentive for further investigation and investment in western Jalisco and Tejope. On the newly acquired Cinco Minas the Daly interests undoubtedly build an ample cyanide plant as soon as the necessary tests and experiments can be made, and for the copper ores of the Magistral it is probable that Mr. Clark will erect a large concentrating mill, more or less on the plans of the former owners, who contemplated a 100-ton mill with the Sutton-Steele dry tables. At the properties of the Los Reyes Mining Co., at Los Reyes, near San Sebastian, for which the Daly estate was negotiating but could not come to terms, all production has been cut off, and for the next four months the underground work will be limited to the development of the mine, and the lixiviation plant has been closed down to allow for the installation of a 25-ton cyanide plant, which will shortly be increased to 200 tons capacity if the results from the small plant are as satisfactory as the laboratory tests have led the company to believe. The San Pedro Analco, above mentioned, is changing from the patio to cyanidation, and will erect a 500-hp. hydro-electric power plant below its dam on the Santiago river. The Tajo mines and tunnel, also controlled by the MacKeever Bros., with L. C. Malone in charge, continue developing the high-grade silver ore struck about 500 ft. from the mouth of the adit in September, and a 10-stamp and cyanide mill has been ordered from Chicago, which should reach Etzatlan, for transport to the properties at San Sebastian, before the end of November. The Casados, near the Molonos, northwest of Hostotipaquillo, is making a fine showing in 50-oz. silver ore, and W. R. Ramadell, of Etzatlan, president of the company, is in the States for the purpose of contracting for a 25-stamp, concentrating, and cyanide plant. The Virginia-M. & S. Co. is putting in a 300-kw. electric power-plant for operating the new mill, which consists of 30 stamps, Willey crushers, compressors, mechanical sizers, and belt-conveyors, etc. The Pennsylvania Copper & Gold Mining Co., near Amea, is preparing to put in a 100-ton concentrating plant, and George McCormack is said to have sold his Zapote copper mine, just south of Amea, through L. C. Grace, to Mexico City people for $35,000. The Palo Quemado, Ampliación del Palo Quemado, and Productora, in Hostotipaquillo, have been bought for $40,000, by R. L. Mayfield, of Shreveport, La., who is interested in the Aztec Queen (known as the Hueldivela mines), which is planning for a 400-hp. hydro-electric plant for mines and mill on the Compestela river, and for which the concession has been obtained. Spokane capital has taken over for $50,000 the Matarunba, in the Mascota district, which has a splendid old record, and work will be done in the proper. T. P. Hard, as general manager in the Bautista and Parnaco districts, south of Amea, it is stated that Monterrey capitalists, headed by Vicente Ferrera, have invested $250,000 for valuable mining interests. And 115 miles southwest of Guadalajara, on the Zapotlan branch of the Mexican Central railroad, and about 18 miles east of the station of Zapotlitic, another Monterrey capitalist, Andres Garza Galan, has proved up a good body of coal under some 2500 acres, with indications that the field covers over 6000 acres. Surveys are already being made by E. D. Cruise, former engineer for the Southern Pacific, for a railroad from Zapotlitic. In Tejope, the Certomina, on the proposed line of the Southern Pacific, and owned by Leurgan & Stanhope, of Ixtlan, has been purchased by Elia Randolph for $50,000, and J. P. Case has been placed in charge. Plans are being drawn up for a mill and a hydro-electric power plant.

In the northern part of Chihuahua the resumption of work is announced on the properties of the Candelaria Mining Co., at San Pedro, on the Rio Grande, Sierra Madre & Pacific railroad, under the management of George A. Laird, of Smith & Laird, Bisbee, Arizona. The properties consist of the San Pedro, Candelaria, Congresso, San Nicolas, Leon, stamp and ores. Accounts, particularly La, who is also working, and operations will at first be confined to the Candelaria, Congresso, and San Nicolas. Considerable unwatering and sinking will have to be accomplished before production on the required scales can be undertaken, for it being a large lead proposition of medium grade, it will be Mr. Laird's endeavor to obtain the largest possible production with the most economical handling, and his experience at the Victoria mines, in San Luis Potosi, and the Sierra de
Cobre mines, in Cananea, have taught him the handling of large tonnage. Automatic devices will be used where possible, and a switch will run from the San Pedro station to the mines, a distance of a mile and a half. Shipments should begin before the end of January, 1909.

**PARRAL, MEXICO.**

**Less Production. — Cause of Decline. — Character of Ores. — Minas Nuevas.—The Tecolotes.—El Rayo.**

Parraí and Santa Barbara shipped 15,000 tons of ore and concentrate in the month of October; this is a large decrease from the normal production. The fall in the price of silver and the depressed financial conditions are chiefly responsible. While nearly all the ores carry lead and gold, the silver content is the dominant and controlling factor. The grade varies and it is difficult to arrive at an average, but ore running 500 grams silver, 15 gm. gold, and 7 to 30% lead may be considered typical of the shipments. In general ores running 500 gm. silver, or lower, cannot be shipped profitably and the mines contain a considerable tonnage of this grade. These ores usually run high in silica, and contain no base metals that cannot be removed by concentration. The gold is finely disseminated through the gangue, and the silver occurs mostly as a chloride, but in some cases as argentite. Ore of this grade and character is found in such mines as the Prieta, Palmailla, El Porvenir, Esperanza, Veta Grande, and Sierra Plata, though all of these have ore of a higher grade than is being shipped. With this condition of the district well-defined, the proposal to cyanide the low-grade ores is receiving most favorable attention. Experiments made on ores of the Minas Nuevas confirm the opinion that it will be possible to revive mining operations by resorting to cyanide treatment of such silicious ore as cannot be shipped while silver remains at its present price. A custom plant for this kind of mill-work seems to be in demand. The El Porvenir, which has the old San Cristobal vein, is taking steps to erect a cyanide plant. Its ore consists of silver chloride and gold in quartz, with apparently little of the base metals. The El Rayo, situated 10 miles north of Santa Barbara, is successfully operating a concentrating mill and cyanide plant on a silicious sulphide ore that runs $15 in gold and $1.15 silver per ton. The base of the sulphide is iron and 40% of the total extraction is obtained from Frue vanners, 60% of the total being cyanided. The El Rayo operations are dissimilar to those proposed for Parraí proper, in that the former has to deal with an ore that is principally gold-bearing, while the latter has an ore essentially silver-bearing and low-grade. So far as the base contents of the two ores are concerned, however, the problems are nearly similar. The Tecolotes, situated close to Santa Barbara, has suffered no month are being made of high-grade gold, silver, and lead ore.

A brief outline of the El Rayo may be of interest, as it is one of the successful mines of the district. The principal vein strikes north on a contact between rhyolite and diorite, having a dip of 50 to 65° west and an average width of 4 ft. The gangue is both quartz and stuccified country rock. It is opened by three levels, which enter the vein at practically the same elevation, making 6000 ft. of drifts on the strike of the vein, with a great amount of stoping above and some winzes below the main adits. The southern part of the mine is known as the Descubridora, the middle as the El Rayo, and the northern end as the El Cobre. It is still being entered by a main adit. The Descubridora and El Rayo portals are at nearly the same point and the ore is hauled to the mill from both over the same surface tramway; another surface tramway from the Adela conveys the ore from that mine to the mill. While there are three main adits, the workings are all connected. The two air-compressors, of Sullivan make, are at the El Rayo. Sullivan drills are used for driving and the Waugh for stoping. The output amounts to 120 tons of ore per day, all of which is milled. The concentrator has one set of roughing rolls, two sets of fine rolls, five Huntington mills, the latter having 50-mesh screens. The rolls and Huntington operate in cyanide solution. The pulp from the Huntington mills passes to 15 Frue vanners, which do all the concentration.
The tailing passes to the cyanide plant, in which the sand and slime are cyanidated separately. The mill is equipped by Wheeler grinding-panels which are used for re-grinding the sand. First, Merrill cones will be installed to separate the sand from the slime as the pulp passes from the Huntington's; the sand will then be re-ground to 80 mesh, the slime to pass directly to the agitator-vats. The re-ground sand will go to the vanners and the vanner falling to the sand-vats for leaching. The solution in the slime-vats is strengthened by the addition of cyanide and lime, from which the whole contents are pumped to the Butters filters. After the solid material is discharged from the filters, the solution is passed to the sand-vats, where additional cyanide is introduced. Finally the gold solution is drawn from the sand-vats, passing through a cone where zinc dust is added, thence to a filter-press in which the precipitate is collected.

Here follows J. S. Colbath's system of discharging the solution into the leaching tanks. This system is, as he states, an improvement on the old practice. He uses no acid treatment. Bert Peterson is general manager, with G. V. B. Leving as assistant manager, and J. S. Colbath, metallurgist.

**BUTTE, MONTANA.**

**Standard Oil Interests in Copper.—Utah Consolidated. — The Anaconda Fire. — Serious Problem.**

For some time the report has been current that interests allied with the Amalgamated and Cole-Ryan concerns had secured control of the Utah Consolidated, one of the big low-grade copper mines. This report is false. The company had authorized the making of a new 10-year contract for the treatment of the company's ores, to take effect upon the expiration of the existing contract with the Garfield plant of the American Smelting & Refining Co. It was stated that by the terms of the new contract the Utah Co., without the investment of any capital, would have $990,000 per year over the expense of treatment under the existing contract, and the company would not be put to the expense of building its own smelter. At the time the new contract was made was not intimated that the contract was given to new interests, or rivals of the American Smelting & Refining Co., but it developed later that John D. Ryan and Thomas F. Cole, closely allied with the Amalgamated Copper Co., represented the new interests in the Utah Co., and that they will build a new smelter for the treatment of that company's ore. They have taken over the land options held by the Utah Co., and it is stated that the new interests have also obtained control of the company itself. The new smelter will cost several million dollars, and is to be one of the largest and best equipped in the West. It will be able to take the ore of any of the Utah companies. The extension of Amalgamated and Standard Oil influence in the copper industry is gradual, but very sure.

For nearly twenty years the fire in the Anaconda mines has been a serious problem; it has again made necessary a temporary suspension of operations in the Neversweat and Anaconda workings, which adjoin and connect. The fire started in the St. Lawrence in 1839 and has been spreading and increasing ever since. The year before the mine was flooded and the fire driven to such a small area that it could be walled in and controlled. Much of the fire territory has since been mined, but the shifting ground, due to the extraction of ore, has frequently in the past two years opened crannies and allowed gases to escape, making mining impossible until the mines could be cleared of the furnaces. Several times during the past ten years the agreement considered it safe to mine some large pillars of ore that had been left as a wall against the fire. About a week ago the fire became so intense in the vicinity of the No. 9 shaft that the flames broke into the shaft and flared above the mouth of it. The flames were soon extin- guished and no damage was done to the shaft itself, but a steady stream of sulphur smoke and fumes issued from the burning copper sulphide ore. A week later the fire broke out unexpectedly on the 1609-ft. level of the Neversweat. Three horses were suffocated and the men were driven out of the mine. The Anaconda mines, on account of the gas in the shaft of that property, had been mined through the Neversweat, but with the outbreak of fire in the latter it became necessary to close the three connecting mines. The fire situation is a serious one.

**JOHANNESBURG, TRANSVAAL.**

At the meeting of the Langhaege Deep, Ltd., Louis Re-yersbach referred somewhat curiously to the company's possible participation in "a combination of interests in its immediate neighborhood," and further aroused public curi- osity by suggesting a new venture in the formation of a company, to be known as "Rumors," the purpose of which would "create the largest individual gold producer on the fields, though by no means the one possessing the largest mining area; at the same time it will ensure to holders highly satisfactory returns for an almost indefinite period of time." In making this claim, Mr. Reversbach had, of course, in his mind a scheme of consolidation resulting in the formation of a single company, which will produce the recently united East Rand Proprietary. This company, with 820 stamps employed, is crushing 140,000 tons per month for a yield of £220,000 and a profit of £120,000. In American money, these returns may be placed at $13,000,000 and $7,000,000 per annum, in round numbers. It is not surprising, therefore, that speculation should be rife as to the exact scope of the newly proposed amalgamation which is to surpass these records. Rumor has it that the mines involved comprise the Crown Reef, Crown Deep, South Rand, Robinson Central Deep, Langhaege Deep, and Paarl Central. The South Rand, now in the shaft-sinking stage, will certainly be united to the Crown Reef, whose 'mynpacht' section is nearing exhaustion, and whose 120-stamp mill is near the South Rand shaft. That the Crown Deep should enter the scheme also appears to stand in the normal order of events, for its workings have already been extended into the South Rand on the dip, while the Robinson Central Deep has always been closely allied with the Crow Deep. As the Langhaege Deep has been definitely stated to be a candidate for membership, this mine may also be placed as a certain unit. Analyzed on these grounds, it would appear that Rumor presents a reasonable case. On the basis of present performances, the group would record the following results:

<table>
<thead>
<tr>
<th>Tons Milled per Month</th>
<th>Yield</th>
<th>Profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Langhaege Deep</td>
<td>39,655</td>
<td>£22,124</td>
</tr>
<tr>
<td>Crown Deep</td>
<td>24,800</td>
<td>10,592</td>
</tr>
<tr>
<td>Crown Deep</td>
<td>40,460</td>
<td>65,973</td>
</tr>
<tr>
<td>Robinson Central Deep</td>
<td>32,300</td>
<td>67,798</td>
</tr>
<tr>
<td><strong>Totals</strong></td>
<td>137,915</td>
<td>£230,287</td>
</tr>
</tbody>
</table>

These aggregate yields and profits do actually exceed those of the East Rand Proprietary, without taking into consideration the large number of companies in amalgamation. That the Paarl Central will also contribute is a further factor supporting Mr. Reversbach's prediction as to the pre-eminence of this great consolidation of interests upon the West Central Rand.

A feature about a small new mill being designed for the Barnies Consolidated is that it will be equipped with an independent amalgamating room, situated apart from the amalgamation. That the Paarl Central will also contribute is a further factor supporting Mr. Reversbach's prediction as to the pre-eminence of this great consolidation of interests upon the West Central Rand.
nift of the I. G. B. profession. In connection with amalgam stealing, it may be incidentally noticed that upon many of the mines an effort is being made to supplant native employees in the reduction works by whites, if not exclusively, as much as possible.

The practice of working on day-shift only underground is proving successful upon two or three of the leading mines. Not only is a saving effected in power costs—when the plant installed happens to be capable of meeting all requirements during the reduced time—but advantage is taken of the superiority of work performed by the men during the day-shift. Of course, the scheme is quite applicable to the majority of mines wherein high-pressure work for two shifts is necessary to keep the mills supplied. In those mines which have adopted the principle of single-shift mining, shoveling and tramming is still undertaken by day and night.

The rate of gold production in the Transvaal continues to advance. Returns for September balanced, within 200 ounces, the output for August, although a short month. The total for the nine months compares with the yields for the last five years as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Gold Production (ounces)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1903</td>
<td>12,589,248</td>
</tr>
<tr>
<td>1904</td>
<td>12,634,896</td>
</tr>
<tr>
<td>1905</td>
<td>20,826,674</td>
</tr>
<tr>
<td>1906</td>
<td>24,579,957</td>
</tr>
<tr>
<td>1907</td>
<td>27,466,735</td>
</tr>
<tr>
<td>1908 (9 months)</td>
<td>21,917,995</td>
</tr>
</tbody>
</table>

The figures for the nine months, viewed in the light of probable immediate increases, show that the 1908 aggregate will approximate £30,000,000. Of the Transvaal total, the Rand accounts for about 96.5 per cent.

Just as certain portions of the Rand or certain minerals sought in the outside districts come in for waves of popularity in the stock market, so do particular devices or subjects enjoy a ‘boom’ of debate in technical circles. At the end of last year and the beginning of this, the stopes-drill—notably as a substitute for hand-labor in case of shortage—was the foremost and almost exclusive topic.

Before referring to the questions now largely before the engineering world, it may be well to refer once again to the issue of the stopes-drill contest, details of which were freely published in the American technical press. It may be recalled that the South African Mining Journal organized a contest, which included several types of ‘baby’ drill and was won, hands down, by the Gordon hammer drill. This machine, equipped only with 2½-hp. plunger, attained wonderful speed records, and proved itself so greatly superior to its rivals throughout the trials, on surface and underground, that the highest hopes were formed of its successful introduction throughout the Rand. Unfortunately, the greater test of many months’ practical adoption under diverse working conditions has now proved that it is quite incapable of maintaining the high place won under perfect trial conditions, in the hands of an operator deemed one of the most highly skilled adepts on the field. It has failed owing to ‘fitchering’ troubles and to excessive wear and tear. But because the South African Mining Journal’s enterprise resulted in giving the laurels to a drill not suitable, in its present form, to Rand conditions, it does not follow that effort has been wasted. On the contrary, it provided an admirable drill reference for the generator contest to be held next year under the auspices of the Government and Chamber of Mines, when the danger of misinterpreting wonderful test-showings will be more easily avoided.

At the present time, Rand technical literature is being enriched by a number of ideas dealing with all questions of communication between mine and surface. Telegraphs and signaling are being discussed in several aspects. Last week a paper was read before the Transvaal Institute of Mechanical Engineers, describing a new device for the automatic recording of mine signals and also of the winding operations. It is intended to act as a safeguard in providing an absolute check upon all signals given, call or reply, and as a useful record of work done and time taken. The inventor refers to it as “a strict and indepen-

dent arbiter in all disputes which may arise in connection with the winding apparatus, and remaining at all times a friend to the good and honest workman.” The apparatus, which has been in use for six months at the Langlaagte Block B mine, comprises a simple clockwork arrangement, carrying, upon a small cylinder, an endless paper band, which is marked by a needle whenever a signal is transmitted. This traveling chart is sectioned so that the time of recording is known precisely. A disc indicating the revolution of the hoisting drum is brought in contact with the paper by means of an electric circuit automatically made and broken by a switch operated on the centrifugal principle from the crank-shaft of the engine. No extra wiring is necessary for the application of this recorder, which can be placed, if desired, in the manager’s or engineer’s office. Such a check upon signaling and hoisting must certainly have a beneficial influence upon all concerned, though perhaps it may be considered somewhat severe upon the engine-driver. A paper read by Mr. Kestner, also before the Transvaal Institute of Mechanical Engineers—soon to

be aptly re-named the South African Institution of Mechanical Engineers, with, probably, corresponding members of council in the chief industrial centres of the sub-continent—has turned anew the thoughts of Rand technical controls to the applicability of high-lift centrifugal pumps for mine drainage. Generally speaking, our pumping problems have been of no peculiar difficulty. The day of the time-honored Cornish pump is passing with the general increase of depth exploited, but it is early yet to say that such popular units as electrically driven three-throw plungers are on the road to the scrap heap. It has been realized that this field is favorable to the centrifugal scheme, as opposed to plungers, in that power is cheap and skilled labor costly—the latter consideration being important when the greater wear and tear in the parts of any reciprocating machine are noted. Certainly the plunger pumps attain a high efficiency, but maintenance costs are also high. Mr. Kestner’s paper, which puts the case for centrifugals (chirally favored on this field for light service around the reduction plant) in the most favorable aspect, will no doubt lead to further comparative investigations. It may be mentioned that in the Kimberley diamond mine Cornish pumps (employed to a depth of 1500 or 1900 ft.) were followed by motor-driven three-throw plungers, and then by centrifugals; these are reported to give the highest satisfaction.

Map of the African Goldfields,
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Lumber cut in the United States in 1907 was 7% greater than the cut for 1906.

The United States is the greatest producer of copper; then Mexico; then Spain.

Eight pounds of water evaporated per pound of coal is an average performance.

The Miocene ditch, at Nome, was built by W. L. Leland, William Bliss, and G. M. Davidson.

The fuel value of dry wood is approximately proportionate to its weight, irrespective of the species.

A nautical mile, or knot, as adopted by the U. S. Coast and Geodetic Survey, is equal to 6080.27 feet.

The miner's inch represents a flow of 1.5 cu. ft. per minute; and the term 'slice head' represents a flow of 60 cu. ft. water per minute.

In pyritic deposits, the content of copper shows a gradual decrease in depth. This is true of Rio Tinto and Tharsis, in Spain; also of typical deposits in Norway.

Naturalization of a father operates to make citizens of only such of his foreign-born children as are under 21 years of age at the date of the parent's naturalization papers.

The copper from the Boleo copper mine, in Lower California, Mexico, is sold at Swansea and Dunkery. On the basis of the average price six weeks before and after arrival of the shipment at the refinery.

A floating crane of 150 tons capacity has recently been built in Germany. The barge carrying the crane, a boiler, and an electric plant for operating the crane, is 150 by 60 ft. and 13 ft. deep. The height of the crane above the deck is 230 feet.

Re-location, used in the correct sense, is the act of making a subsequent location differing from the previous one in the position or size of the claim, while an amended location is made to correct an error or errors in the legal papers used in the previous act of locating.

The genesis of the Mt. Lyell copper deposit is attributed by Gregory to metasomatic replacement in crushed material along fault-planes. The pyritic minerals of the schist are secondary, and there is evidence that the ore has been formed after the schist was foliated.

The principle of the storage battery was discovered in 1801, by Gauntherot, who experimented with platinum electrodes immersed in a salt solution. However, it was Gaston Plante who, about 1860, produced a battery having sufficient capacity to make it a commercial possibility.

Along the coast of the South Island of New Zealand there is an enormous accumulation of auriferous gravel, up to 300 and perhaps 500 ft. thick, capped in places by glacier drifts, which, having been intersected by more recent streams, have supplied a large quantity of gold.

There is no invariable association of copper and any particular igneous rock. Diabase in New Jersey, granite in Montana, are examples. Igneous contacts with limestone are favorable. Copper is found in sandstone in many regions, such as Russia, Germany, Bolivia, and Central Africa.

Sulphate of lime is the worst scale-forming constituent of boiler feed-water. To test for its presence, add a little chloride of barium to a few cubic centimetres of the water. If a white precipitate is formed which will not dissolve on the addition of a drop or two of nitric acid, sulphate of lime is present.

Electrolytic iron always contains hydrogen in varying quantities, according to the conditions under which it is deposited, and the more hydrogen it contains the greater is its hardness. The hardest varieties will scratch glass. Iron highly charged with hydrogen is very inert, and not readily attacked by acids.

In the ordinary mechanical jig a speed of 300 rev. per minute is about the maximum, with a minimum stroke of, say, 2 to 4 mm.; and even with this, there is much strain on the parts and corresponding wear and tear. The regular beat of the plunger causes too great a rush of water, and that carries upward the minute particles of ore.

Pure hydrogen manufactured with a simple apparatus and from non-bulky materials, is the achievement of recent French experiments. Fine aluminum filings are mixed with a small proportion of mercuric chloride and potassium cyanide, which causes a slight rise of temperature, and produces a coarse powder, quite stable if kept dry. This powder is treated with water, about 1 litre to a kilogram, and the temperature, as the hydrogen is evolved, is kept below 70° C. by the addition of more water. At that temperature 21/4 lb. are completely oxidized in two hours, and yields 44 cu. ft. of pure hydrogen.

Serpentine is unknown in crystalline form, always occurring massive, in spite of its possessing a definite chemical composition. Chemically it is the magnesium salt of di-silicic acid, its formula being \( \text{H}_2\text{Mg}_3\text{Si}_2\text{O}_7 \), showing it to be a hydrous orthosilicate. The formula is generally simplified to \( \text{H}_2\text{Mg}_2\text{Si}_2\text{O}_7 \). The mineral has a hardness of 2.5 to 3. It is smooth, and has a greasy feel. The color is usually a shade of green, sometimes brown and white. Specific gravity, 2.2 to 2.7. It is always secondary, resulting from the alteration of silicates containing magnesia, such as olivine. The alterations may be illustrated by the following equation (after Pirson):

\[
\text{Olivine} + \text{Water} + \text{Carbon dioxide} = \text{Serpentine} + \text{Magentite} \\
2\text{Mg}_2\text{Si}_2\text{O}_7 + 2\text{H}_2\text{O} + \text{CO}_2 = \text{H}_2\text{Mg}_2\text{Si}_2\text{O}_7 + \text{MgCO}_3
\]
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Explosion in Compressed-Air Main.

The Editor:

Sir—Referring to my letter appearing in your issue of August 22, on the subject of an explosion in the compressed-air main of the Tonopah Mining Co., I wish to present some further facts concerning the explosion. It may also be of interest to mention the causes of such explosions, together with the precautions for preventing trouble of this kind, that were considered by our management after an investigation of the Mizpah explosion, and a thorough discussion of it. No serious claim for originality is made. Such authorities as were obtained were freely consulted; Peele's new book, 'Compressed Air Plants for Mines', being especially helpful. I shall refer to the explosion in our plant as the Mizpah explosion.

The plant in question consists of two 2-stage compressors, one a Fulton compressor, cylinders 25 and 15 by 18 in., running 120-125 strokes per min.; the other an Ingersoll compressor, type D2, cylinders 22½ and 14½ by 18 in., running 120-125 strokes per minute. Both compressors have unloaders of the throttled intake type, are water-jacketed about the cylinders, and have inter-coolers between the low and high compressioned cylinders. At the time of the explosion the compressors were connected with two 4 by 10-ft. receivers, one for each compressor, and the two receivers were connected to the main. Since the explosion a receiver, 6 by 16 ft., has been added to the system.

The explosion took place on the evening of a fair day, at 6:30 p.m., about 45 minutes after starting the compressors. It occurred in the 6-in. main, between 100 and 400 ft. from the receivers. The explosion was violent, and burst open most of the pipe between the 300-ft. level and the surface. The woodwork in the shaft to which the pipe was fastened did not show any searching, thereby indicating that this portion of the pipe was not excessively hot at any time prior to the explosion. The usual working-pressure is 90-95 lb., but at this time it was only about 80 lb. The compressors were known to be working hot, but as no thermometers were in use it is not possible to state the temperature. In the attempt to improve conditions, the cylinder-oil being used was changed to one having a higher flash and ignition-point, but even with this oil, combustion, but not explosion, has occurred in the receiver attached to the Ingersoll compressor.

Among the unfavorable conditions under which the plant works are the following: An atmospheric temperature frequently in the neighborhood of 100°F. during the summer; an altitude of 6000 ft.; and an Ingersoll compressor designed for sea-level. The Ingersoll compressor was installed first, later the Fulton was added, and various other minor additions were made from time to time as their need was felt; consequently the plant lacks the uniformity of design it would have had if it had all been installed at one time.

The cause of this kind of explosion is obviously the presence in the system of an inflammable gas, or possibly dust, mixed with air in such quantity as to render it explosive. The presence of an inflammable gas may be accounted for in several ways:

1. It may be generated from an oil of low flash and ignition-point by a not unreasonably high temperature.

2. It may be generated from an oil of high flash and ignition-point by an excessive temperature.

3. It may be generated by high temperature from a tarry deposit of partly destroyed oil, carried over from the compressor. This is sometimes deposited in the pipes or receivers of compressors.

Among the ways of accounting for the presence of fine carbonaceous dust are:

1. Dust from outside sources, such as coal-dust from the blacksmith shop, drawn through the intake. This would probably be insufficient by itself to cause explosion.

2. Smoke generated by over-heating of oil or tarry deposits. This would doubtless be accompanied by gas, and may be considered as a part of the gas, as far as its effects go.

Ignition of the explosive mixture may have originated in the Mizpah explosion, in the following places:

1. In the main where the explosion occurred. This seems improbable. The timbers show no charring such as would be caused by hot pipes.

2. In the receiver. This seems possible.

3. In the pipe between the compressor and the receiver. This seems possible. It is here that a black sooty or tarry deposit is sometimes found.

4. In the cylinders or in the outlet pipe, due solely to a sudden increase of temperature caused by leaky or sticking valves, improper unloading devices, or by an outlet-pipe choked with carbonaceous deposit.

Wherever ignition occurred, it may have been caused by the catalytic action of a porous deposit of carbon, even though the general temperature were not high enough to ignite the gas under ordinary conditions. To quote from Ostwald's 'Chemistry': ‘The oxidation of many substances by free oxygen is greatly accelerated when charcoal is present . . . Gases which under given conditions set only slowly on one another can be made to set more quickly with the help of charcoal.’

If ignition occurred in the compressor, or in the outlet-pipe to the receiver, or in the receiver, we must account for the explosion occurring only in the main and not in the receivers. I would explain this by assuming that the receivers were filled with a mixture of gas and air in such proportions as to be inflammable but not explosive: that the mixture was explosive only in the main, and that combustion of the gas in the receivers was comparatively slow, in the nature of a flare, and served to transmit ignition to the mixture in the main. In a letter on this subject, Prof. Edmund O'Neill says: 'The most favorable mixture is about one part of oil vapor to seven
parts of air. As the proportion of oil vapor or air
recedes from this proportion the violence of the ex-
losion diminishes until there is no danger either way.
The most violent explosion may occur with less
air or with more air, according to the composition
of the gas." From this it will be seen that we can
have a gas-and-air mixture spread throughout the
receivers and pipes, varying from a merely inflam-
bable mixture in one place to a highly explosive
mixture in another place. The heat of the flare
would raise the pressure in the receiver and thus in-
crease the pressure of the mixture in the main and
render its explosion all the more violent.

It is the purpose of the company to carry the in-
vestigation further. To this end, recording pressure-
gauges have been attached to the compressors, and it
is planned to insert thermometers, some of them self-
recording, in various parts of the system. By these
means we shall be able to record the temperature
and pressure under all conditions. It is also planned
to have the lubricating oils tested, and to watch the
amount and kind of deposits left anywhere in the
system. By these means we hope to ascertain the
causes of trouble in our plant and to avoid them.

The precautions deemed advisable are as follows:

1. First, where possible, a well designed plant,
built for the altitude in which it is to operate. With
a sea-level compressor working at a high altitude, too
great a proportion of the work is thrown on the
high-compression cylinder. Under this heading
come the following details:
   (a) Intake-pipe of wood and taking air from a
       place outdoors as cool and as far away from dust-
       producers, such as the blacksmith shop, as possible.
   (b) Unloader to be of a design that will not
       cause excessive heating when the compressor is
       partly unloaded. Some unloaders, especially of the
       throttled-intake type, seem to have this tendency.
   (c) Efficient intercoolers.
   (d) After coolers between the high-compression
cylinder and the receiver, on a compressor that shows
a tendency to overheat. This would tend to prevent
the transmission of ignition into the receiver, even
though gas were formed, and the gas would not igni-
nate spontaneously in the receiver if cooled before
getting there.
   (e) Efficient water-coolers, where water must be
       used over again.
   (f) Inlet to receivers to be at their top, and out-
       let about a foot above the bottom. This will insure
the air entering the main being clean, and the cool-
est in the receiver.
   (g) Blow-off cock at bottom of receiver.
   (h) Check-valve between compressor and re-
       ceiver. This may save the compressor in case of an
explosion or flare in the receiver.
   (i) Recording thermometers and pressure-gauges.
2. Use the best oil obtainable for the purpose,
and as little of it as is consistent with proper lubri-
cation. It would seem that a good oil, with as high
a flash and ignition-point as can be produced with
the necessary fluidity, would be the most desirable;
for a poor oil would doubtless furnish the condition
for explosion at a lower temperature than a good oil.

3. Use well regulated oil-cups with sight feed. If
oil is fed in excess of the requirements of the pistons,
it will accumulate in the cylinders, when they are
unloaded, as there is no opportunity for it to be
blown off with the air. In machines where overheating is apt to occur, this gives a favorable condi-
tion for gas production.

4. Clean the outlet valves once a week.

Referring again to my letter of August 22, I wish
to correct the statement in it regarding an explosion
in California of a compressor belonging to the Stand-
ard Oil Co. My information on this subject was hear-
say, and I have since been informed on good author-
ity that there was no such explosion in any of the
Standard Oil Co.'s plants.

J. A. BURGES.

Tonopah, Nevada, October 22.

Standardizing Engineering Publications.

The Editor:

Sir,—The important consideration to the specialist,
in any branch of engineering, is how to make his
store of information, his professional notes and the
works of others, readily accessible, that the informa-
tion may be called to hand when needed with the
minimum expenditure of time and effort. Time,
which is a fixed element, is a most valuable asset;
effort spent otherwise than in productive work is
force dissipated. The specialist, in order to practise
successfully, must have his knowledge and his work-
ing information so marshalled that they constitute
a treatise in his branch. How best to accomplish the
economical collecting and filing of notes and informa-
tion becomes an important question. The object
of this letter is to suggest a step in the direction of
improving the conditions under which we work.

The record of current practice in engineering, the
examples of recent construction, and the presenta-
tion of scientific data and research are made through
the following mediums:

2. Technical periodicals, published weekly or at
   other short intervals.
3. Technical magazines, published monthly or at
   longer intervals.
4. Publications of the engineering societies and
   scientific associations.
5. Publications and reports of the various depart-
   ments of the Government.
6. Reports of public commissions, and municipal
   and State officers.
7. Information spread in pamphlet form, from
   miscellaneous sources.
8. Trade and manufacturers' catalogues and bul-
   letins.

We depend upon practically all of the above
sources to keep abreast of developments in any par-
ticular line of work. It is difficult to designate which
is the most important; perhaps the technical paper
has the broadest usefulness because it reaches the
widest field. The plea of this letter is for a stan-
dardization of the size of the pages for all publica-
tions, in order that information upon a special sub-
ject printed in any one of the forms may be segre-
gated from the balance of the matter contained in a particular issue and filed separately in a special binder. There is some question as to the advisability of including books, as such, in the list, for their form makes it impracticable. The objection does not hold, however, against the remaining seven styles of publications. The prevailing loose-leaf form of notebook, as developed lately, points unmistakably, by its extreme usefulness and flexibility of adoption, to the wisdom of advocating its extension in the field here considered.

It is realized that to advocate a step so extreme as this will call forth protests from many interests, and it may provoke the risibilities of some. To bring out a discussion upon the soundness and desirability of the idea is the first consideration. If it be deemed sound and useful, then the concerted effort of the members of the profession can be used to promote ways to make it practicable.

Referring first to the technical paper, it is made from a standard sheet of paper, ordinarily 24 by 36 in., 26 by 38 in., 36 by 48 in., or 36 by 52 in. dimensions. These sheets when printed, cut, and folded make pages of various sizes. To illustrate, there was found recently on a table in a certain office the following enumerated papers:

<table>
<thead>
<tr>
<th>Periodical</th>
<th>Net size of page</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power</td>
<td>9 by 12 in.</td>
</tr>
<tr>
<td>Electrical World</td>
<td>9 by 12 in.</td>
</tr>
<tr>
<td>The Foundry</td>
<td>9 by 12 in.</td>
</tr>
<tr>
<td>The Engineering and Mining Journal</td>
<td>9 by 12 in.</td>
</tr>
<tr>
<td>Engineering-Contracting</td>
<td>9 by 12 in.</td>
</tr>
<tr>
<td>The Architect and Engineer</td>
<td>7½ by 10½ in.</td>
</tr>
<tr>
<td>The Iron Age</td>
<td>8½ by 12½ in.</td>
</tr>
<tr>
<td>Mining and Scientific Press</td>
<td>8½ by 12½ in.</td>
</tr>
<tr>
<td>Engineering Record</td>
<td>10½ by 13½ in.</td>
</tr>
</tbody>
</table>

The list is presented as one taken at random. Of the mining journals, five are 9 by 12 in. and the remainder, with one exception, approximate those dimensions closely. To carry out the idea of standardization to its useful end, the sheets should be cut in assembling so that each is bound singly within the covers. The familiar wire-clip can be used as at present for fastening the sheets, after which the back can be gummed. When the journal is in the hands of the subscriber it can be punched for loose-leaf binding with the ordinary desk form of punch, brass fasteners inserted with the thumb put in place, and the wire-clips may then be removed. Having put the journal in this shape, articles on particular topics may be removed at will to the special binders.

The objections to adopting the idea will come primarily from the publishers. The probable objections will be discussed briefly: a technical journal is, from the standpoint of the publisher, a medium for the display of advertising. The revenue from advertising must carry the paper or it ceases to be published; practically all the news-print of today derives its existence from that source. The advertiser who is displaying his goods to the engineer and to the trade is the factor to consider. By careful analysis of the situation, it is seen that he will be the one to gain the greatest benefit from the changed conditions, for it must be admitted that the value of nearly all advertising matter is lost as it is handled now. The advertising presented to our review is not of the class shown on the city bill-board where a new brand of whiskey is being exploited, which advertising is treated as a public nuisance; on the contrary, it is a positive and definite assistance in keeping abreast with new developments. When a manufacturer calls attention to a new type of dredge, a new gear-cutting machine, or to a tape of a new metal whose coefficient of expansion and contraction is almost a negligible quantity, he is doing the profession a service and the matter is eagerly read. Immediately his advertisement is slipped from among the leaves of the journal and is filed in the binder reserved for that particular topic. The files under the head of "dredges" are as quickly filled with the advertising showing the various types of, and the names of the various manufacturers of, dredges as they are with subject-matter on performances. Is the advertiser the loser thereby? It can hardly be conceived how such could be the case when by one stroke he gains the point sought in all efforts toward publicity: that of having the constant attention of the particular public sought to be interested. Is the publisher going to lose custom? Not when the customer finds that his advertising is being treated in this more intelligent manner, is being filed systematically, and indexed for ready reference.

It is felt that if a movement could be started to bring the technical papers to see the great advantages, both to themselves and to the profession and the trade, of a sheet of standard size, it would require less effort to induce other publishers to follow that lead. The Government probably would be hardest to move in this respect. The publications and reports of the various departments contain vast stores of knowledge and research, which it is the avowed purpose of the Government to disseminate broadly. How limited is the circle reached! When an engineer moves his library, the books, papers, and pamphlets he generally leaves behind are the Government 'tracts'. These, if had in another form, would be carefully preserved.

San Francisco, November 12.

J. H. G. WOLF.

[The reading matter on each of our pages covers a space of 7½ by 11, while that on the 9 by 12-in. page occupies 7 by 10 inches. The reason for adopting the size of 8½ by 12½ was to give the Mining and Scientific Press the proportions of a book: the 9 by 12 dimensions give a shape so nearly square as to be extremely ugly when the issues are bound in a volume at the end of each half-year. Another reason for making the Mining and Scientific Press different in size was to make it distinctive, departing from a 'standardization' that involved the idea of using this form of trade literature solely as a lure for advertising. Except The Iron Age, the other periodicals mentioned are mostly syndicate papers, forming part of enterprises controlled by speculative publishers, to whom the reading matter is merely an adjunct to attract advertising display. The Mining and Scientific Press is unwilling to become one of the standardized syndicated trade-papers, and emphasizes the fact by a difference in shape and type.—Entron.]
DREDGING ON THE SEWARD PENINSAUL.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

No less than 65 dredges have been built and operated for the extraction of gold from the gravel deposits of Alaska and the Yukon. It cannot be said that either the Canadian territory or its American neighbor afford a proud record in this branch of alluvial mining. Of the 65 dredges mentioned, at least 35 come under the category of ‘things to avoid,’ for they were mechanical eccentricities, in the contemplation of which there is as much pathos as humor; in the construction of them the ignorance of their designers was joined with the most superb disregard for all previous experience. Of the 30 dredges remaining after the foolish schemes are subtracted, 18 failed on account of faulty construction, frozen ground, or lack of gold, as well as from sundry other difficulties common to human industry, such as poor management, unskilful operation, accidents. Thus there remain 12 dredges that are rated as successes, both technical and financial. It would be invidious, if not dangerous, to particularize further, but for the present purpose it may be said that only one out of these 12 successful dredges is on that romantic, spacious, and rich peninsula named after the Secretary of the Interior associated in history with the transfer of Alaska from Russia to the United States.

Anyone desiring to obtain an epitome of dredging on the Seward Peninsula has but to take a stroll in the environs of Nome, especially along the meandering estuary of the Snake river. On the shores of that serpentine expanse of brackish water there lie stranded several abortive (Fig. 1) that at one time or another were doubtless heralded as ‘gold ships’ of assured promise. Incidentally, never invest your money in a dredge that is labeled a ‘gold ship,’ it is a term invented by a sophomoric reporter, and employed by the incubators of wild cats. A dredge is not a ship, but a strong machine placed upon a scow, so that the digging of the bank of gravel, and the extraction of the gold, may proceed concurrently and continuously. That is just what the derelicts on the banks of the Snake failed to do; if they did any digging, the amount was small and spasmodic; if they saved any gold, the quantity was insignificant and insufficient. Several, dipper-dredges, with paddle-wheels at their stern (Fig. 2 and 3), decorate lugubriously the shore of the lagoon west of the city of Nome. To an Oroville man they would seem like the nightmares of a distempered dream. There are also sundry steam-shovels, some of them of inexplicable design, and as well fitted to operate in gravel deposits as to prepare ground for planting cabbages. Around the bend of the Snake river, near the Wild Goose pump, I saw a washing plant joined to a steam-shovel, a relic from the boom days, and a suggestion that experience may be disregarded as long as the gullibility of mankind endures. In this locality, half a dozen dredges are within sight at one time, not counting wrecks the real character of which wind and weather have obscured. Of all the machines in the Snake estuary, only one was at work during my stay at Nome, and this was operated for only a few days. I refer to the Wisconsin dredge (Fig. 4), owned by Bursiek & Co., of Cleveland, Ohio. This machine was shipped to Nome in 1900, and in September of that year it was thrown by a big storm far inland upon the tundra. The buckets are of 3 ft. capacity, and resemble in shape and size an ordinary fire-bucket; they are attached to a filmy sprecklet-chain. The revolving screen is made of wire, and discharges to one side upon a belt-conveyor extending rearward along the upper deck so as to reach beyond the stern for a distance of 20 ft. The fine gravel passing through the screen flows along 60 ft. of sluice-boxes, and descends into an iron chute. The nominal capacity of the dredge is 1200 cubic yards; the actual capacity when at work is 400 to 500. On September 7 this dredge was being laid up for the winter, not because the season was ended, but by reason of a break-down. The spud was smashed, several sprecket were broken, and the machine was in trouble generally. No wonder; it had been operated on ground that had been leased and was supposed to contain thawed gravel. The ground had not been drilled or otherwise tested. As soon as the open-connected bucket-line of infantile design ‘bucked’ the frozen ground, something had to yield—and it was not the gravel frozen to the firmness of granite. There is a touch of humor in the remembrance that this Wisconsin dredge, owned in Ohio, is at least nominally connected with two States that manufacture some of the best dredging machinery ever built, and if the gentlemen at Cleveland care to use such ancient contraptions as this Wisconsin dredge, it is not for lack of accessibility to something better.

One of the tributaries of the Snake river is Bourbon creek. This is a depression in the coastal plain north of Nome; it forms a shallow little valley that has been the scene of several attempts at dredging, most of which are associated with the name of Powell. During the past summer a large dredge started to work in this locality, and furnished another sad commentary on the lack of wisdom exhibited by people usually rated as of more than average intelligence. I refer to the enterprise of the Nome Mining Co., controlled by several well known officers of the United States Steel Co. This dredge has proved a fiasco. Nor were warnings lacking. Along the bottom of Bourbon creek, both above and below the big new dredge, there stood several mute witnesses to human stupidity in the form of dredging devices of archaic design. Some idiot evidently thought that he had got hold of an idea overlooked by engineers versed in this branch of mining, the fact being that his idea had been thrown on the scrap-heap of discarded inventions more than ten years ago.

When I first saw the Bourbon Creek dredge (Fig. 5) it lay with its back broken, under water, for an accident had happened a few days after the first start. The full extent of the injury was not known, but it was expected confidently that repairs could be made rapidly, and that a successful run would follow ere the close of the short season. The dredge
was stated to be a copy of 'California No. 3', at Oroville, but this is incorrect, for 'California No. 3' is a 7½ ft. Marion machine of excellent design. The Bourbon Creek dredge has buckets of 9 cu. ft. capacity, close-connected, and was assembled by E. L. Smith; the machinery was supplied by the Taylor Iron & Steel Co. The nominal capacity was 120,000 cubic yards per month, and it was expected that 3000 yards per day would be dug. The cost of the dredge is stated to have been $97,000, and the power-plant adjoining, $115,000. At a first glance it appeared that the hull was too weak for the digging machinery, and the gantry too light for a dredge of such power. Also the washing apparatus seemed inadequate to cope with the supply of gravel raised by the buckets. The gravel is small, it is mostly what dredge-men call 'chicken feed'. More than 50% of the material raised by the dredge passed through the 3/8-in. holes of the screen, as against 20%, the proportion more usual in California. In consequence, the washing-tables were crowded. The screen is 6 ft. diam. and 32 ft. long, giving 27 ft. of screening surface; yet it was not big enough for the purpose intended. The chafing-beams are horizontal along the sides of the well instead of being placed vertically; in consequence, the buckets in their swing tend to strike the chafing-beams and to pull them off. Something of this sort caused the accident, the bucket-line being allowed to sag so as to strike the side of the pontoon when the dredge moved into a new position. The hull was torn and the water entered, drowning the dredge. The tumbler is made wholly of manganese steel, instead of the wearing parts only. When the tumbler wears, the worn part cannot be replaced and the whole casting must be scrapped. This is an inadvisable deviation from modern practice. The bucket-line is operated by a gear-drive from a motor placed on the tumbler-gantry above the deck, the result being to suspend unnecessary weight upon timbers subject to vibration. These are some of the criticisms prompted by an examination of the dredge, and the sequel proves the fairness of them, for after making sundry repairs and re-floating the dredge, another worse accident followed forthwith, so that the effort to operate was abandoned, pending the re-building of the machine and the engagement of a man able to direct the operation.

It is worth while to tell the story of this fiasco, not to hurt the feelings of anyone concerned, but as a warning likely to be needed in the course of the next two or three years, when I expect to see many new dredging enterprises started in the North. On careful enquiry, I ascertained that the first trouble was due to inexpert handling of the dredge. The flotation was insufficient at the start, and the dam was too low. Soon after beginning work the dredge dug into an old drain (wooden conduit), and this allowed the water in the pond to escape; the dredge was laid on the ground with one end overhanging, so as to "put a crimp" in the hull. After the dam was repaired, re-filled, and the dredge re-started, the ladder had a heavy side-pull and the slack chain was dragged against the side of the well, tearing a hole in the pontoon. This caused the boat to sink one side first, and, the ladder being then on the bottom, the whole weight (600 tons) of the dredge was thrown upon the end of the ladder, breaking the heavy steel cast-
MINING AND SCIENTIFIC PRESS

steel and not enough in either the hull or the head of the manager. The man in command was an engineer from the iron mines of Minnesota, wholly inexperienced in gold mining. Knowing nothing of dredging, it might be supposed that he would go to Orovile or Marysville and engage a capable dredgemaster; instead, he placed an electrician in charge. Whatever defects the dredge may have had, these were magnified by unskilful handling.

Dredging is usually preceded by drilling. The Nome Mining Co. owns 43 claims, the defunct dredge being on No. 6 Below Discovery. I was informed that 200 holes were drilled, the plan being to drill 9 holes per claim of 20 acres in that part of the property likely to be dredgeable. The average yield was given to me as 75 cents per cubic yard, and the record indicated that the gold was distributed in layers at intervals throughout the vertical section. The log showed that gold was found all the way down, with enrichment at 10 and 20 ft., and also just above bedrock itself. The bedrock is soft schist, well adapted to this kind of mining. The poorest drill-hole yielded at the rate of 13c. per yard. The depth of digging at the site of the dredge was 35 ft., and the top of the tundra forming the bank of the creek was 20 ft. higher. On some of the property the depth to bedrock was as much as 80 ft., and the drill-record showed an average of $1.17 per yard in this deep ground. The lowest average for any one claim was 31 cents. Although the holes ranged in depth from 28 to 80 ft., the average yield was obtained by adding the weight of the gold extracted from the different holes and dividing the sum by the number of holes. This is a childish error. Moreover, the log shown to me was not such as to inspire confidence; it was in bad order and exhibited errors in the calculations. Even the manager knew so little about the character of the ground he expected to dredge as to tell me that F. G. stood for 'frozen ground' when it meant 'fine gravel', the idea of 18 or 20 ft. of frozen ground being enough to dismay even a 'tenderfoot'. On the whole, this enterprise exhibits all the blunders it is possible to make in dredging; if you must make it certain that failure will result, then place the testing of the ground in capable hands and allow the records to become muddled, build a cheap dredge with an expensive power-plant, hire a colliery engineer or an architect to manage the affair, and let him place an electrician in charge, so that the last chance of success may be eliminated. Then go ahead cheerfully and expect miracles to happen.

The Bourbon Creek dredge is within half a mile of the town of Nome. About three miles farther north, and in the first watercourse to the west, is another dredge, in course of construction. This is on Wonder creek. It is a substantial machine, and represents the re-modeling of a double-lift dredge that was built to operate on Nome river. It is not likely to be completed before the close of the present season.

On September 3 I visited Ophir creek, about 85 miles southeast of Nome, and in the course of that journey saw several dredges. Upon No. 1 Below Discovery on Ophir creek, the Blue Goose Mining Co. is operating a dredge that was originally erected in 1905 on the Ninkluk river, near Council, and dug its way up that river and up its tributary, Ophir creek, for a distance of four miles, to the present site of operations. The dredge has buckets of 5 cu. ft. capacity, close-connected, turning over a hexagonal upper tumbler and a pentagonal lower tumbler. The buckets empty into a hopper, lined with steel plates, and thence the material passes over a sluice 4 ft. wide and 22 ft. long provided with cast-iron (Hungarian) riffles. Here as much as 90% of the gold is caught. Then come two shaking screen-tables, made of perforated plates, each 14 ft. long and with a movement in opposite directions. The perforations are 5/16 and 5/32 inch, successively. On the screen-tables there are obstructions or stops (made of cast iron) so as to retard the flow of the gravel and disintegrate any clay. The shaking-screens have a 6-in. stroke, and the eccentrics run smoothly. Water is raised to the head of the top sluice by a 10-in. Morris sand-pump, which also elevates the drip from the 'save-all' in the well. The dredge is digging 14 ft. under water; there is no bank above water except an occasional foot or two of old tailing from early ground-shieving operations.

On the very evening of my arrival a serious accident happened, necessitating a complete stop to digging. Three of the teeth of the main driving-wheel were broken; a fragment of a tooth had become caught by the pinion, and this had cracked the cast-iron rim of the driving-wheel itself. The large wooden spud was shattered. But it took only three days to complete the repairs. A new spud was available and replaced the shattered remnants of the old one. The broken teeth were replaced by three stub teeth or pegs fitted into holes drilled into the rim of the driving-wheel and riveted firmly in place. Two steel bands (on each side), and another underneath, strengthened the cracked portion of the driving-wheel and made it stronger than before. These bands were riveted through the rim. Of course, the main gear-wheel of a dredge should not be made of cast iron, but it must be remembered that this was an old machine, and those in charge had to do the best they could. And they did well. I would like to see the same superintendent and crew in charge of a standard dredge.

The accident was due to frozen ground. When anything goes wrong with a dredge in the North, cherchez la glace! The experience of the last two seasons has proved that there may be from 6 inches to 6 feet of frozen ground, usually well above bedrock. The driving-wheel had been cracked three times, and on each occasion it was repaired as described. The last accident was due to an encounter with frozen gravel, then dropping the buckets into unfrozen bedrock, so that the buckets struck the frozen ground in their ascent. This frost is not original, but is due to pools of stagnant water left in old workings, for the dredge is working the site of early diggings. Originally the entire creek was thawed naturally, as is frequently the case where water runs, and the surface was covered with scrub willows—an
unfailing sign of unfrozen ground. The secondary frost, due to formation of ice from the freezing of water in old workings, is not so hard as the original frost, that is, the glacial condition characteristic of the surface throughout the North, except in creek-beds. Powder is used to shatter the frost under the top dirt. In the spring a way was cleared for the dredge by blasting the ice formed in old wing-dams, and it was expected that the water brought to the spot by a ditch would assist in thawing the ground; but this expectation was not fulfilled: the ice was broken rather than dissolved, and in places the ground was re-frozen. Next season it is intended to work a face 500 ft. wide, and remove the overburden down to frost (1 to 6 ft.) for a distance of 18 ft. ahead of the face. By the time the dredge returns to the end of a cut, the gravel will have thawed a couple of feet, enough to facilitate another move forward. There is said to be difficulty in using steam-points in ground partly thawed because the flow of water is controlled by the winchman.

As the gravel passes from the top sluice onto the operations of the Blue Goose dredge, I wish to refer to the arrangement for washing the gravel. These are excellent. As previously stated, as much as 90% of all the gold saved is arrested by the cast-iron riffles in the first sluice. In mining, always catch your gold as soon as you can; never depend upon a second operation or device if the first will do the trick. In shooting ducks it is best to get your bird with the first barrel and not depend upon the second, even though it be choke-bored, for by that time the duck may have flown out of range. As the bucket empties into the hopper, a heavy vertical jet of water plays upon it, so as to ensure the washing of any fine gold adhering with clay to the bottom of the bucket. This jet is used only when washing bedrock, and drill-hole chokes before the point can be put in position to be of service. There has never been a day this season that this little dredge has not worked ground partly frozen, though the first 'perpetual' frost was that struck on the day of my first visit, when the spud and bull-wheel were broken. It was all due to one small spot that had not thawed, although all around the ground had softened. The bedrock itself was soft enough to be dug under the layer of frozen gravel. These details are worthy of record, for insistence upon them will serve to remind the reader of the great obstacle to dredging in the North. The obstacle is insuperable, by any means, but the attempt to ignore it constitutes the main reason for so many fiascos in dredging.

Before giving figures relating to the secondary works and development of the mine, I wish to say that there has been a great deal of progress. There is not the least slowness to the work. One point about it is the fact that the work is carried on during the winter season, for there is much game in the region and the operators are able to get all the men they need.

Next season it is intended to work a face 500 ft. wide, and remove the overburden down to frost (1 to 6 ft.) for a distance of 18 ft. ahead of the face. By the time the dredge returns to the end of a cut, the gravel will have thawed a couple of feet, enough to facilitate another move forward. There is said to be difficulty in using steam-points in ground partly thawed because the flow of water is controlled by the winchman.
the shaking-screens it is retarded by the stops already mentioned, and in its passage it receives the strong spray under 204 lb. pressure, issuing from ¾-in. pipe drawn down to ½-in. nozzles. These jets turn over the flat pieces of bedrock and wash the gravel free from clay, to which particles of gold may adhere. A second row of jets lower down repeats this process. It can be noticed that the jets of the last row have the effect of arresting the flow of material, so as to send the water through the screen, while the tailing reaches the belt-conveyor (of the stacker) in an almost dry condition.

When working full time this dredge raises 1000 cubic yards per day. It digs from 1 to 4 ft. of bedrock, which is a soft schist. On the pontoon there is a machine-shop, smithy, and mess-room. The crew take their mid-day meal on board, and when the dredge is at work they must feel like the passengers on a Yukon steamer aground. During the season of 1907 this dredge worked for 110 days. The actual running-time represented 69% of the total time. The ground excavated represented 98,718 cu. yd.; the total expenses were $31,672, and the value of the gold extracted was $83,144. Therefore the average yield was 84 cents and the average cost 32 cents per cubic yard. The season of 1908 will show about the same costs, but a better yield of gold. The fuel consumed is wood, at the rate of 10 cords per day, at $10 per cord delivered. The total costs as given above include all repairs, equipment, and general expenses. The dredge cost $28,700; it was a small and poorly equipped machine, therefore repairs entail $5000 each season. The manager is G. H. Russell, and the president of the company is Jafet Lindeberg. To both these gentlemen I am indebted for more than the usual frankness and courtesy.

On the way from Ophir creek to Solomon, in the valley of the Solomon river, I saw several dredges and one that was in action. This was near the mouth of Big Hurrah creek; it was a small machine, actuated by a gasoline motor, and it was coughing loudly under the strain of laborious digging. At Oro Fino, near the mouth of Shovel creek, on the Solomon river, two dredges are in operation, both of them important enterprises. The Nome-Montana-New Mexico dredge had started only a few days before my visit, and was hardly working to its normal capacity. It is a Risdon machine, with open-connected buckets of 5-ft. capacity, turning over a quadrilateral top tumbler and a pentagonal lower tumbler. The stacker is a close-connected bucket elevator, the buckets being shallow, like pans. The revolving screen is sectional, 4½ ft. diam. and 26 ft. long. There are 240 square feet of gold-saving tables and in addition there are side shives. Cocoa-nut matting is laid under riffles of expanded metal, as is customary on dredges built by the Risdon Iron Works. It is a good gold-saving device. The bow-gantry has a strong square frame, capped by a steel I-beam. This dredge is not new; it was built in 1905 for a company operating on Cook’s Inlet, the machinery being moved and placed upon a new hull. The present owners control 110 acres of dredgeable ground on the Solomon river. At the time of my visit the buckets were coming up nearly empty, the dredge was digging in hard limestone, and seemed to be laboring under difficulties. Gerald H. Hutton, a capable dredge-master from New Zealand, was in charge. This dredge, overloaded with hyphens and struggling with hard bedrock, did not give an immediate impression of success. It seemed not to be strong enough, and the question arose why the owners of the ground had not asked the Risdon foundry to make them one of their most modern dredges, instead of employing a second-hand machine. I learned that J. P. Pearson, the promoter and general manager, considered that he was getting a bargain. The hull is new, and the dredge was made ready in the record time of 50 days. While it was bucking into hard limestone at the time of my visit, further enquiry proved that the dredge-master was cutting into the rima-rock in order to make room preparatory to turning the dredge. For the first two weeks the yield was poor for this reason: after September 6 the dredge began to dig in profitable gravel. While the start was not made until August 24, there were 55 days of actual operation up to October 19, when the season ended. The dredge dug 42,000 yards of gravel in 49 days, at an operating cost of 14.6 cents per cubic yard, burning only 4 tons of coal (at $2.175 per ton) in 24 hours.

A hundred yards away, the Three Friends dredge was emitting steam and ejecting broken limestone with a cheerful regularity that suggested profitable exploitation. I approach the description of this enterprise with keen pleasure, for this is the one perfectly sane, sound, and successful dredging operation on the Seward Peninsula. It was organized by W. L. Leland. Mr. Leland, a Californian accustomed to the atmosphere of practical mining, was one of three men that built the Miocene ditch. The ‘‘three friends’’ were Frederick H. Ringde, Charles A. Giffen, and W. L. Leland. The dredge cost $118,000. It is modeled after the ‘‘Exploration No. 2’’ at Oroville, and started to work in June, 1905. The buckets are of 5 cu. ft. capacity, close-connected, with a 12-in. lip. The capacity is 3700 cubic yards per day. Washing of the gravel is effected on a tabular shaking-screen, built in two sections, one lapping over the other and moving contrariwise. The upper section is 7 ft. 5 in., and the lower 7 ft. 9 in. wide. Each is 14 ft. long. Owing to the overlap, the total working length is 24 ft. This screen-table is made of ⅓-in. hardened steel plate, punched with holes, tapered and tempered. The openings grade from ⅕ to ⅓ in. diam. Strong jets of water play upon the gravel as it travels down the shaking-table. Owing to the absence of clay, the shaking screen proves thoroughly efficient. The tailing is dry and clean as it falls upon the belt of the stacker. The stacker is a belt-elevator moving at the rate of 280 ft. per min. Saving of the gold is effected by means of Hungarian riffles, in three tiers (2½ by 7½ ft.), arranged in zigzag immediately underneath the screen. The effect is to interrupt the flow of the material and to arrest the movement of the gold before it reaches the side tables, where more riffles are in service. No cocoa-nut matting is used,
The bucket-line is actuated by a driving-gear that is double, so as to equalize the strain on the tumbler-

Movement forward is effected on the spud, the dredge swinging by its side lines while digging.

shaft. Both the upper and lower tumblers are provided with wearing-plates of manganese steel, in order to avoid the necessity for scrapping the entire casting (that costs $8000) when it becomes worn. A pneumatic riveter and chisel has proved a great convenience for repairing the buckets.

When a cut is completed, the bucket-ladder is pulled up, the dredge 'steps' ahead on the spud for a distance of about 6 ft., and the buckets start digging into the surface. At the end of each swing, over an arc of 100 to 125 ft., the ladder is dropped sufficiently to permit the buckets to take another cut of
2 ft. out of the bank. At the time of my visit the dredge was digging to a depth of 16 ft. This is clean gravel, for the cover of surface dirt does not exceed one foot in depth. By courtesy of Mr. Le- land, the dredge was stopped while our party examined the tables under the electric lights. The deposit of gold, some of it amalgamated but much of it free, was of the most encouraging character. On ascending to the upper deck and watching the operation of digging, we obtained an idea of the nature of the operation. It was highly creditable to the builders of the dredge. At this time the buckets were digging into a limestone, removing 18 in. to 2 ft. of the hard rock. The fragments in the buckets looked as if they had passed through a rockbreaker. It is the practice to dig into the bedrock until the dredge refuses to go deeper, no attempt being made to force it beyond the limit of safety.

On moving to the stern it could be seen that the dredge had been digging in limestone for several days; previously the bedrock was schist. Of the total area to be dredged, 80% is schist. On the tailing-piles I saw chunks of weathered limestone 2 to 3 ft. wide; these lie on the bedrock, the gravel consisting largely of rock similar to the underlying formation, and varying accordingly. When working on hard bedrock, at a depth of 18 to 20 ft., for example, it is customary to have 7 or 8 buckets dragging on the bottom, with the weight of the ladder on top of them, so as to cause them to take hold or bite into the rock. With 7 buckets working thus, there is 16 ½ ft. of effective scraping machinery in operation along the top of the bedrock.

The result is that a smooth surface is left in the wake of the dredge, all the gravel and top bedrock being removed completely. Certainly, even to one who has seen a dredge before, it was surprising to observe how the buckets were digging below the weathered limestone into the fresh hard rock.

The property of the Three Friends Mining Co. covers 4000 acres, of which 1400 are being patented and only 70 acres have been worked out, in three seasons. The season is 4 months, plus from 5 to 10 days. The operating cost, including winter expense, is 10½ cents per cubic yard; the total expense, including depreciation, maintenance, and amortization of capital, is 13 cents. The cost for fuel, using 14 tons of coal per day, at $2.22 per ton, is $3500 per month. The dredge has made a record for steady running, doing better than an average of 23 hours per day for an entire season of over 4 months. Frozen ground has been avoided.

Last spring the dredge encountered a bit of frozen ground where no frost was supposed to exist. It was due to ice formed during the previous winter. In three weeks the lips of the buckets were worn away 3½ inches through their 11½ in. of manganese steel, the toughest metal as yet discovered for such operations. Later in the season this particular place was found to have thawed. It is now planned to work in the willows for 4 or 5 weeks before attack-

ing the river bar. Willows indicate thawed ground. The winter cold penetrates deeper in the clean gravel of the creek than in the debris of the bank. Whatever river-ice survives into the early summer is due to the winter frost, for the creek freezes solid 12 to 14 ft. deep. In tackling the frozen gravel, it was found that the buckets sliced the pebbles, the frozen mass of material being as completely cemented as a conglomerate that has undergone metamorphism. But those three weeks in frozen ground caused as much wear and tear to the dredge as 10 months of ordinary work. The manager knew what he was about; he dug just enough of the frozen ground to enable him to float the dredge and move it forward into the thawed area.

This dredge has worked for three seasons, and while the figures of production are not available for publication, I can state that the profit has already exceeded the cost of the dredge and its installation. A ditch is being built with a view to the erection of an electric power-plant and the construction of another dredge. At present the cost of power represents two-thirds of the total operating expense. In California the cost of power on a dredge is $850 to $1100 per month, in this case it is $8500. The contrast is forcible. Furthermore, the operation of a single dredge is not economical if the area to be worked is large enough to warrant the employment of more than one dredge. The general management remains the same, whether one dredge is operated or more; also the question of repairs is simplified, for the cost of carrying a stock of duplicate parts is shared by the larger number of machines. Mr. Leland keeps $19,000 worth of repair-parts on hand for the existing dredge. Obviously, it is a pity that the two dredges of the two companies operating on adjacent ground were not sufficiently similar in design to permit of the use of identical wearing-parts.

It is pleasant to leave the description of dredging on the Seward Peninsula at this point, for the Three Friends is an enterprise that sustains the belief that dredging is a profitable form of industry if properly undertaken. Mr. Leland spent three seasons in testing his ground by drilling; he supervised the drilling operations himself, and obtained results that were absolutely reliable. Then he went to Oroville, the place where dredging practice was best developed at that time, andascertained what service different types of dredges had given. Having found the one that was rated as the most efficient, he ordered a copy of it (with minor modifications) to be manufactured by a reliable foundry, and finally he selected men (to erect the dredge and to take charge of it) who had had experience in such matters and had a good record. This procedure seems obvious, and it does not appear to require any special inspiration. Most people hate to spend money in testing their ground, for such work yields no gold; they like to try a new machine, for man ever runs after what is new; they think it proper to put a nephew or a friend's uncle in charge of their affair. Then things happen. I have emphasized the human aspect of my story because it is one that is certain to recur in the development of the North.

LA PLATA MOUNTAINS, COLORADO.

Written for the *MINING AND SCIENTIFIC PRESS*  
By R. H. Toll.

The La Plata Mountain district is one of the Rip Van Winkle mining districts of Colorado that have been asleep for many years and are just attracting the attention of capital. It has been roused a number of times before, but on commencing to stir it has been hit in the eye by some marauding speculator. This time, however, it really seems to be coming back to life, for the steady output of the last few years has demonstrated that it has considerable bodies of rich ore and is really worthy of exploration.

A remote situation, in the southwestern corner of the State, has been chiefly responsible for the lack of interest in the district, investors preferring to spend their money in camps closer to Denver, the remoteness being enhanced by the method of running the local trains. If you go from the north you must spend the night in Telluride; and if approaching from the east you are obliged to lose 16 hours in Durango, although within an hour’s ride of the main entrance to the district, and although the trains run through to Silverton without change. This places the La Plata mines one day farther from Denver by rail than either of the chief camps of the San Juan.

The camp is an old one. Beginning its existence in 1873, when the discovery of rich ore on the Comstock, on the La Plata river, created an excitement that attracted people from all parts of the country and built up a number of prosperous agricultural communities, though the difficulties of transportation and redenomination of ore at that time nipped production in the bud, so that the mining boom gradually faded away. Parrott City, the first town in the county, was built at the portal of La Plata canyon and was for several years the county-seat. The Comstock was gouged out to a depth of 75 ft. and abandoned almost without any development, although the ore was sufficiently rich to be hauled to Pueblo by oxen, a distance of about 300 miles, netting $60,000 to $70,000.

Most of the orebodies so far discovered have been small, but the ores are rich and a number of the mines have made excellent records, which would have created a stampede had any of them been situated within the bounds of the bustling State of Nevada. The possibilities are illustrated by the fact that the May Day, which has produced more than a million dollars, was discovered only about four years ago within half a mile of Parrott City, on a trail which had been used by prospectors for thirty years. When the prospect was 20 ft. deep, the fortunate finders disposed of the claim for $50,000 and it has ‘made good.’ Some of the shipments are said to have averaged $1000 per sack.

The La Plata mountains constitute a compact group of high peaks resulting from a domal uplift, which apparently had its centre in Waterfall gulch, at the head of Lightner creek. According to Whitman Cross this upheaval took place in early Tertiary times, but was entirely independent of the San Juan uplift, which preceded. The district covers an oval area 12 to 15 miles in diameter and is cut in all directions by a complicated system of dikes, sheets, and laccoliths, chiefly of acid lavas, such as diorite, syenite, and the intermediate rock, monzonite. The ejection of these masses, causing local uplifts and cracking the sedimentaries, was, of course, one of the principal factors in determining the present topography by influencing erosion; and such peaks as Silver, Lewis, and Mt. Moss, which are wholly or partly laccolithic, stand out prominently as erosion centres, from which the streams radiate with remarkable regularity in all directions like the spokes of a wheel, all ultimately finding their way into the waters of the Colorado river.

South through the central portion of the district flows the principal stream, the La Plata, which has eaten its way by head-water erosion far into the northernmost hills and has built rich placers in the lower end of the canyon and on the level bars at its entrance; but of such depth and containing boulders of such size that they have not been profitable. The highest mountain of the group is Hesperus, 13,225 ft., which is a remnant of the uplift produced by the eruption of Mt. Moss, a laccolith adjoining Hesperus on the north and which shoots out a number of intrusive arms between the sedimentaries of the surrounding hills and tilts the strata so sharply that the Manes shales, which compose the uppermost peaks of Hesperus, are at least 7000 ft. higher than on the gentle slopes of the Manes valley and the Dolores plateau, only a few miles distant.

One striking feature of the geology of the district is the absence of Primary rocks. There are no exposures of granite and the only known granitic rocks in sight are limited exposures of schist and gneiss in the extreme portion of the district. By far the larger portion of the mountain area is covered by sedimentary rocks, chiefly of the Mesozoic age, though in the eastern part a few strata of the upper Carboniferous appear. The most important of the sedimentaries are of the Triassic period, the lower member of which (the Dolores formation) is about 2900 ft. thick and appears in all portions of the district. It is made up of calcareous sandstones, siliaceous limestones, shales, grits, and conglomerates, generally of a brilliant red, owing to the dissemination of a fine-grained pigment of iron oxide and minute crystals of pink feldspar. This formation corresponds to the Red Beds of the eastern slope of the Rocky Mountains.

Locally these brilliant hues have been altered by metamorphism and hydro-thermal action to purple, brown, yellow, and dazzling white; and these colors, mingled with the dark-gray of the porphyries and the lighter grays of the stock-rocks, the dark-green of the dense vegetation wherever it can obtain a foothold, the black stripes of shale and the irregular patches of shining black where manganese abounds, impart to these hills a singular beauty. The canyons of the West Manes and Juncton creek present as magnificent seckery as is to be found anywhere in the State.

The lower member of the Dolores is composed
The mining districts of the Mancos formation differ from those of the Jogazine in the system with which they are associated, the great thickness of the Mancos beds, the uniformity of their sedimentary structure, and the greater frequency of dike-traverseings. The Mancos debris has been so uniformly worked that it is now impossible to distinguish the outcrop of any one deposit. The beds are exposed in a series of cliffs, and the various minerals have been widely dispersed over the country. The great thickness of the beds, the uniformity of the stratification, and the considerable development of the dike-system, make the Mancos formation the most important mine in the district.

The La Plata mining district, Colorado.

The La Plata mining district, Colorado.

formation of such size and importance as to have given it the name of the district—the La Plata sandstone. It is usually nearly white in color, very silicious and of great thickness, forming prominent cliffs, especially at the head of the two main branches of the Mancos river, where the nearly vertical cliffs are 200 to 500 ft. high, broken only where the strongest fissures cut through them. This is of Jurassic age, of which the upper member is composed of the innumerable thin strata of clay-shale of the MeElmo formation. Above these lies the Dakota sandstone and the Mancos shale, of the Cre-taceous.

Between the sedimentary strata, notably those of the Jurassic period, occur beds of ore known as 'blanket-veins' and 'contacts,' though the latter word means nothing in this case beyond the fact that the joint-planes between the strata have afforded a path for the percolating solutions and have thus given them an opportunity to attack the contiguous portions of the rock, removing the more soluble constituents and replacing them with metallic minerals. These deposits show their greatest development in the vicinity of eruptive rocks, from which doubtless their valuable contents are derived. On the Portland Boy, at the head of Bedrock gulch, near an immense dike of monzonite, which forms the divide between the Mancos and the La Plata, one of these deposits is 10 ft. thick; and on the Doyle properties at the head of the East Mancos river, no fewer than five of these ore-beds are exposed on the side of Treasure ridge, which apparently is traversed from end to end by a body of monzonite and contains numerous bodies of rhyolite and diorite and is cut by a number of fissures, several of which are gold-bearing veins of economic importance. None of these ore-beds have been developed to any great depth, though short adits have been driven at frequent intervals on them all for a distance of a mile or more along the outcrop, giving the hill very much the appearance of Gibraltar from a distance.

The principal one of these deposits, which is the lowest one exposed, has one adit nearly 500 ft. and has produced in the neighborhood of $50,000, with considerable rich ore still in sight in the workings, although the mine has been closed down practically ever since it was acquired by Mr. James Doyle, several years ago. The property is provided with a 10-stamp mill, electric plant, Dur-kee drills, electric pumps, etc., and a lot of fine buildings, testifying to the vagaries of an impractical manager who preferred the adornment of the surface to the expenditure of his funds underground. Most of this ore is low-grade but there are bodies of rich ore and under judicious management these properties should do well, for they were profitably operated by the original owners, who treated the ore in a little mill consisting of two Tremain batteries, plates, and a double-deck Wilfley. The concentrator was evidently more ornamental than useful, for the entire saving was made on the plates and no concentrate was shipped, although the tailing impounded will assay over $20 per ton. The operators were not practical mill-men and the ground beneath and below the mill is heavily charged with quicksilver and amalgam; the fact that their last run, of 21 hours' duration, produced a retort worth $2900 illustrates the richness of some of this ore.

In this portion of the district the important metal is gold; practically no base metals occur, except iron and some copper. Over all other parts of the La Plata mountains the gold and the silver are equally
important; and tellurium, bismuth, arsenic, antimony, mercury, lead, zinc, and other metallic elements are associated in the ores.

The district has suffered from the financial depression, but still there is work going on all over the southern and eastern slopes of the mountains. On the East Manesos river are numerous promising prospects, in addition to the mines already mentioned, although little but the annual assessment work is now being done. The Old Kentucky, which has been idle for two years, is about to resume operations, and bids are asked for raising 80 ft. and sinking 200 ft., it being the intention to operate in the future by shaft, the best ore so far developed being below the adit-level. The Gold Dollar is working a small force on a good-sized vein having a pay-streak 16 in. wide, from which a shipment to the Durango smelter a few days ago returned $41.50 per ton.

On the La Plata river several mines are in active operation and making a remarkable showing. At the mouth of the canyon is the May Day, previously mentioned, which has produced close to $500,000 net and is shipping 8 to 12 ears per month with a force of about a dozen men underground. It is equipped with steam-power plant, air-drills, a Crane ore-washer, electric lights, and the buildings are excellent in design and convenience. A wire-robe tramway connects the ore-house with the shaft half-way up the mountain, but this has been put out of commission since the completion of the adit near the base of the hill, through which all operations are now conducted. This is the loading-place for all mines along the river, the Rio Grande Southern railroad having built a switch two years ago connecting this mine with the main line, three miles away.

The ore of the May Day, like most of the rich ore of the district, is a telluride, chiefly petzite and sylvanite. Adjoining this property on the north, the Valley View is working about 15 men on development, making monthly shipments of high-grade ore similar to that of the May Day. It is equipped with power-drills and a Crane washer, and has a good showing. It is said to have produced about $80,000.

Across the gulch is the Movaratz, one of the early locations, which was idle thirty years and revived last year. Here a bed of black limestone close to a body of diorite-porphyry has been impregnated with galena carrying 20 to 30 oz. silver per ton, and some good ore is being produced, of which a shipment will be made soon.

Up the river a mile from the May Day, the Little La Plata is producing some excellent ore, and will soon enter the shipping list, though the workings are hardly away from the grass-roots; and across from the Comstock the Lucky Four is driving a cross-cut to open up several veins that have produced pay-ore high up on the mountain. They are using a Temple-drill operated by a gasoline-engine.

The Bonnie Girl, about a mile above La Plata City, is also undergoing development. The sandstone at this place has been impregnated with auriferous iron-pyrite over a large area and to a depth of two or three hundred feet. Stringers carrying good ore are of frequent occurrence, and near the surface the gold is free; but the entire mass is rather low-grade and has not yet proved profitable. On the river below the mine a large electric plant run by water-power, a 50-stamp mill, and other expensive equipment, including a wire-robe tramway to the mine, were installed three or four years ago; but the mill has been operated only at intervals during the summer months, and the plant has usually been damaged considerably by snow during the winter, so that most of the summer seasons have been spent in making repairs.

In Basin gulch, near the head of the La Plata, the Tomahawk company has been steadily developing promising ground and taking out some rich ore in the course of the work. They have a small steam-electric plant on the river nearly a mile below the mine, and use Temple drills for the level work, coal-augers operated by hand giving most satisfactory results in all vertical work. The workings consist of 1700 ft. of cross-cut and nearly 2000 ft. of drift on three veins along the contact of a diorite dike and red sandstone, the vertical depth being about 700 ft. The pay-streaks vary in width from an inch to two feet or more, and assay well, in places many thousands of dollars per ton, specimen rock being as rich in sylvanite as any seen in the Cripple Creek district. This company has recently taken a bond and lease on the Small Hopes, another old property near-by in Williams gulch, and has commenced development. The Small Hopes was operated 12 years ago and produced a couple of earloads of rich ore from a shaft several hundred feet above the adit now being driven.

West of the Tomahawk is the White Diamond group, on which are a number of veins from 6 to 25 ft. wide, developed by a 700-ft. cross-cut, a 150-ft. cross-cut, several shafts and raises. Assays are said to range from $53 to $10,000 per ton, but probably no systematic sampling has ever been done. About Oro Fino, at the head of Junction creek, much activity is being manifested. Several old properties are resuming work, and two or three good strikes have been made lately. The Neglected, which has been closed down because of litigation for the last four years, is about to resume under new management, and a new plant of machinery will be installed. This property was opened about six years ago by Durango prospectors and made an enviable record, producing, it is said, about $600,000 during two years of operation. The Portland, Fassbinder, Gold King, and Swamp Angel are all under active development and have promising showings. The Portland has a 50-ft. shaft and about 200 ft. of drifts, from which picked samples run several thousand dollars per ton. On the eastern base of Silver Mtn. a five-foot vein has recently been opened which carries about a foot of ore ranging in value from $50 to $100 per ton, practically all silver, with a fraction of an ounce of gold.

A great deal of prospecting has been going on all over the district, with encouraging results; and there are many other old properties, such as the Durango Girl, Democrat, Eureka-Bulldozer, Mountain Lily, Century, Belle Hamilton, Ashland, and others, which produced rich ore many years ago and might
now be re-opened with profit, with the improved facilities for mining, shipping, and treatment. The orebodies as a rule are comparatively small, but the ores are exceptionally rich; and the success of the May Day and Tomahawk at depths of 700 to 800 ft., the deepest workings in the district, proves that the gold and silver persist to a considerable depth, contrary to former opinions of engineers regarding the veins in these mountains.

A description of this district would be incomplete without mention of the promising copper prospects that occur at the head of Bedrock creek and along the divide between this stream and the East Mancos river. Here an area of several square miles is principally monzonite porphyry carrying an appreciable quantity of copper. All this rock, as far as sampled, carries from a trace to 5% copper, while there are many narrow veins carrying copper glance, azurite, malachite, and chalcopyrite; and in the seams and cracks of the porphyry leaves of native copper are found. The water issuing from the porphyry is heavily charged with copper, so that prospectors in the neighborhood of Bedrock gulch have amassed themselves during the past season by precipitating a quantity of metal on tin cans and pieces of scrap-iron placed in the stream.

The only development on these prospects consists of shallow surface workings: but the showing certainly justifies exploration and indicates that these great low-grade bodies may become commercially valuable by operation on such a scale as the mines at Bingham, for instance, which they closely resemble in character.

A cement paste for protecting steel from gaseous fumes has been used by the Pennsylvania railroad at Columbus, Ohio, with signal success. The coating is a cement paste mixed in the proportion of 12 lb. pure red lead, 32 lb. portland cement, 4 lb. linseed oil, and 2 lb. dryer. This mixture should make a paste like putty, but if too soft, cement and red lead are to be added, and if too heavy, oil and dryer are to be added. The method of application is as follows: 1. The iron or steel surface to be coated should be as clean of rust and foreign matter as it can be made, using either sand-blast, steel brush, chisel, or sand-paper for this purpose, according to the amount and hardness of the foreign matter to be removed. 2. Apply one heavy coat of red lead and allow it to set. 3. Apply one heavy coat of Japan dryer. 4. Apply paste on dryer while latter is green; do not allow Japan dryer to become dry before applying paste. The paste should be put on about one-eighth inch thick, rubbed with trowel and pressed around rivet heads and angle flanges by hand. 5. Cover all with one coat of red lead. This last coat adds a great deal to the life of the coating, as it retards the hardening effect of the atmosphere on the paste. The life of the coating is said to be six years, and the cost for labor and material, including the cleaning of the metal, eight cents per square foot.

Oyster-shells are burned into lime at Baltimore. The shells before burning contain about 52% lime and 40% carbon dioxide.

The Prospector.

D. C. McD., Ely, Nevada: No. 1, hematite (black) in altered granitic rock; No. 2, earthy limestone.
C. C. W., Cannonville, Utah: Fragmental rock covered with thin film of iron oxide. The colors are those observed in tempering steel.
H. H. B., Eureka, California: No. 1, fine-grained biotite-hornblende granite, may be diorite in larger masses; No. 2, diorite; No. 3, hornblende andesite.
J. M. Dillon, Montana: Black sand, containing large proportion of magnetite; also large amount of basaltic rhyolites, some spinel and some metallic sulphides; no platinum noted; any assayer should be able to smell the sand.
A. H. C., Pyung Yang, Korea: No. 1, basalt; No. 2, fine-grained crystalline schist; No. 3, spotted schist, derived probably from a basic igneous rock; No. 4, crystalline schist, seems to be a modification of No. 2; No. 5, wall-rock of vein or fissure altered by pressure and mineral solutions, and containing considerable chalcopyrite; No. 6, platy amphibole filled with calcite.
J. A. R., Sylvania, New Mexico: The white to yellowish white mineral with brilliant metallic lustre is tetradyminite, since it has a very good cleavage in one direction and yields excellent tests for tellurium and bismuth without giving any suggestion of sulphur or selenium. On each of several trials it was completely volatile before the blow-pipe, from which it follows that gold is not combined with it. It does contain gold mechanically included in lumps, which are plainly visible and sharply limited. In one place gold was noticed as occurring in a thin layer, partly separating the tetradyminite from a dull gray metallic substance which apparently encloses both the gold and the tetradyminite. Owing to the scanty amount of the substance, its nature could not be determined.
J. A. P., Fairview, Nevada: No. 14, altered andesite; No. 15, rhyolite or andesite, much altered and containing considerable sulphide; No. 16, andesite impregnated with sulphides; No. 17, andesite; No. 18, rhyolite, silicified and containing sulphides; No. 19, surface rock, much altered and silicified, probably rhyolite, but too far decomposed for identification; No. 20, rhyolite stained with iron oxide; No. 21, andesite tuff; No. 22, highly altered surface rock, probably rhyolite, stained green; No. 23, rhyolite; No. 24, bleached and altered rhyolite; No. 25, almost completely silicified rock, rhyolite or andesite; No. 26, andesite altered by hot mineral solutions; No. 27, rhyolite with sulphides; No. 28, andesite; No. 29, iron-stained and partly decomposed rock from surface, probably rhyolite.
SINKING A REINFORCED-CONCRETE SHAFT.

By Louis L. Brown.

*On the flats across the Susquehanna river from Wilkesbarre, Pa., the Delaware, Lackawanna & Western railroad is now sinking a shaft for its Woodward colliery, in the first 80 ft. of which a reinforced-concrete caisson was used to penetrate the extremely wet and porous overlying strata. From borings it was determined that difficulty would be found in sinking through these layers of sand, gravel, and quicksand above the rock strata, which lie about 79 ft. below the surface, especially as the water in the soil maintains about the same level as the river, and the latter varies constantly, at times flooding the whole country. The quantity of water to be overcome in sinking would have been so great, on account of the proximity of the river, that some special method had to be devised for making the shaft water-tight, in order that the subsequent sinking

(Showing nature of country in which it was built. Susquehanna river and Wilkes-Barre in distance.)

*Abstracted from Engineering News of September 24, 1908, by permission of the publishers.
through the rock to the coal-bearing veins could be completed. After considering these features, the railway engineers designed and constructed a reinforced-concrete shaft-wall, which was built above ground and sunk into place by excavating beneath.

The contractors started work in September, 1907. The first operation was to excavate a pit 15 ft. deep, to just above the ground-water. The bulk of this earth was taken out by scrapers, the steep sloping sides being finished with two derricks. The bottom of the pit, roughly 65 by 33 ft., was then leveled and the steel cutting-edge (Fig. 1), 59 ft. 6 in. by 28 ft., was set up and assembled. This cutting-edge or shoe was made of 3/4-in. plate, well reinforced with riveted angles. The outside vertical plate of this shoe was 32 in. high, and the shelf that carried the green concrete, and afterward protected it during the sinking, was 24 in. wide and 8 in. above the toe of the vertical plate.

During the time of excavating a gang of carpenters had been building three complete sets of forms. After the cutting edge had been carefully leveled the first forms were set up and firmly braced, tie-rods as well as ordinary pushing-branches being used. The closely spaced 1 by 1 1/2-in. reinforcing rods were then placed and the concrete deposited. The outside form of this first section was built plumb, while the inside was battered back so that the concrete wall sloped up to a 7-ft. thickness on the sides and a 5-ft. on the ends. The complete design is shown in Fig. 2. Other vertical forms were then set up and concreted until a total height of 20 ft. was reached, when the bottom forms were removed and the caisson carefully leveled and prepared for sinking. Only three sections of forms were used to complete the job. The concrete was machine mixed and deposited in the forms by means of the two derricks and cyclopean buckets. The concrete was mixed in the proportions of 1:2:4. The total reinforcement amounted to 140 tons. The shaft being designed with three compartments, for air, pump, and hoist, the two partition walls were carried up with the other work. These helped to strengthen the outer walls against the lateral earth pressure as the caisson was being sunk.

While it had been considered possible to sink the caisson to rock without the use of compressed air, yet, on account of the great volume of water in the soil, it was by no means certain that the open method would be successful. For this reason the contractors designed a heavy timber deck, and all arrangements were made so that the change from the open method to that of the pneumatic process could be effected without loss of time. The possible use of an air-deck necessitated leaving a recess in all the shaft-walls. This recess was 8 ft. above the cutting edge, and was 9 in. deep and 39 in. high. Fortunately it was not necessary to resort to the pneumatic process, although the point where it would be imperative was practically reached.

Before starting the sinking, two single-acting pumps, of a combined capacity of 1400 gal. per min., were placed on timbers 8 ft. above the cutting edge, and sinking operations started on November 7, 1907. The sinking proceeded both day and night, in two 10-hr. shifts. Each gang consisted of a foreman and 16 men. The material as it was excavated was shoveled into 1 1/2 cu. yd. buckets, which were hoisted by two stiff-leg derricks. These derricks had 45-ft. booms, and as the buckets were hoisted they were automatically dumped into 1 1/2-cu. yd. cars, which were run in on four sidings close to the caisson. These cars were then pulled by mules to an adjoining field, where they were dumped and the empties run back.

In sinking, quicksand was first encountered, then gravel. As the open excavation had been carried down to within one foot of the ground-water line, the pumps had to be started with the very first of the sinking, and by the time the gravel was reached were handling 1200 gal. of water per minute. Under the gravel was found a bed of stiff clay, which reached in some places to the rock, while in others it was underlaid with about 18 in. of peaty gravel. When passing through the clay no water was in evidence. the clay closing around the caisson and preventing the water from following or entering under the cutting edge.

The sinking of such a large mass of comparatively green concrete was, of course, attended with difficulty, requiring the constant attention of experienced men. Inasmuch as one of the shaft-compartments is to be fitted with guides for two elevator cages, the question of plumbness alone was a big factor. Levels were taken at frequent intervals, and the excavation made in such a way that the walls as they sank maintained a practical plumbness. As can be imagined, in a length of 60 ft. soils of different consistencies were found at different points along the cutting edge. The caisson at such times required careful handling. An average excavation of from 90 to 100 cu. yd. per 10-hr. shift was considered good progress.

While the work of cleaning off the rock was in progress, the river rose rapidly and flooded the flats. The increased head resulted in the water being forced down between the clay and the sides of the caisson. This water came in under the cutting edge and rose so quickly that the pumps could not handle it; they were soon drowned and the shaft filled. Extra pumps were immediately ordered and the task of lowering the water was started. The additional pumps were of the piston-packed type, and worked satisfactorily until the water was lowered to about 10 ft. above the cutting edge. Then, owing to the fact that the water carried large quantities of gravel, a great deal of trouble was experienced. The sand not only wore out the packing, but also the water-cylinders to such an extent that the piston slippage was so great that even the largest of the pumps proved inadequate. On this account sufficient extra pumps had to be installed so that the shutting down of any one would not cripple the job. The addition of a motor-driven centrifugal pump of 1000 gal. capacity also helped, and the water was then lowered to below the cutting edge. When the excavation reached the rock it was found that it would be necessary to construct a temporary seal between the rock and the shoe for the whole perimeter. This was done by means of 12 by 12 in. yellow pine blocks and white pine wedges. As the work progressed
6-in. pipe 'bleeders' were left in, to handle some of the water and thus relieve the pressure at the points at which the men were working to put in new blocks.

Owing to the constant fluctuation in the height of water in the bottom, due to numerous troubles with the pumps, and also the difficulty of keeping the sand and gravel back during the work, the final sealing was a slow and tedious operation. After the last of jarring loose any of the temporary sealing blocks or breaking back into the slatey rock, this excavation was started by channeling for a depth of 5 ft. all around the shaft about 1 ft. inside of the blocking. The rock was then taken out in the ordinary manner with two shaft-bars and four rock-drills. To prevent the jarring of this blocking the rock was taken out in 5-ft. benches only. This made the work

blocking had been wedged in place the bleeders were closed and the inflow of water, with the exception of some minute squirting streams, checked. These streams were speedily calked with white pine wedges, resulting in a practically dry bottom.

The next task was to take out the rock to a depth of 20 ft. and build up an underpinning wall to carry the weight of the caisson and make the permanent seal to keep out all water. To avoid the possibility slow, but it was deemed advisable, and so proved, for, notwithstanding every care, certain leakages occurred which made the rock excavation slow, requiring shifting of pumps, taking off and putting back suction pipes, etc. This rock would break back a considerable distance from the line of holes. On this account, upon arriving at the elevation at which the underpinning wall was to start, the rock had to be again channeled for a depth of 5 ft. all round

Fig. 2. Details of the Caisson.
the inside line of the wall. The rock inside this line was then taken out and formed a sump, which enabled the concrete wall to be started on a dry beach. This also precluded any chance of damaging the concrete by the heavy firing necessary in proceeding with the excavation. While this excavation had been progressing, grout had been forced back of the blocking under the shoe by means of a pump operating at an 80-lb. pressure. This gradually cut down the leakage until that remaining about equaled the water which would flow through a 2-in. pipe.

Before starting the concrete underpinning wall, the rock footing was carefully cleaned off and a recess cut in it to form a stout toe for this wall. Various seams in the rock emitted water. This was handled during the building of the wall by fitting a small wooden trough around the wall and leading the water beyond the face of the wall through pipe bleeders. Grout pipes were also inserted in the tops of these troughs, led beyond the face of the wall, and grouted after the concrete had set sufficiently to resist the resultant pressure. To help bond the underpinning wall to the caisson proper, and help carry its weight, the inclined face of the concrete above the shoe was not only roughened, but also had a 1-ft. step cut in it. Fig. 3 shows the method of making the permanent seal between the shaft-wall and the rock. To prevent the possibility of flooding by any high stages of the water in the river the shaft-wall was carried up to 15 ft. above the general ground level.

The merits of the Edison long-kiln system for burning cement may be considered as beyond dispute since the North American Portland Cement Co. has acquired the patents from Mr. Edison. This means that the Edison system will be adopted as standard by the cement trust.

Mineral waters from American sources were sold in the United States in 1907 to the extent of 52,060,920 gal., valued at the point of production at $7,381,- 508, or approximately 1¢ per gallon.

**IRON ORES IN UTAH.**

At present less than 2% of the iron ore mined annually comes from west of the Mississippi, but the Western deposits are now coming into demand. One such deposit, in Iron county, souther Utah, in the Iron Springs district, has been explored by about 1600 pits, but as the deepest pit was carried down only 130 ft., the vertical depth of the ores is not known. Their total tonnage, as far as can be measured, is 40,000,000 tons. The nearest railroad station is 22 miles distant. The ores occur in disconnected masses, within an area 1½ by 20 miles in extent, most of them at or near the contact of limestone and andesite, the latter existing as a laccolith or sill. Iron ores and other minerals were deposited as fissure veins in the andesite and as replacement bodies and fissure veins in the overlying limestone. Finally erosion exposed the laccoliths and the ores. The ores in the andesite may extend down to very considerable depths. The only one of the laccoliths the thickness of which can ever be estimated at present probably does not extend farther down than 2500 ft. The uniform association of ore with laccoliths in this and other Western iron districts outlines the first rule for the prospector searching for such ores—to find the laccoliths and determine their boundaries. The contact with the sedimentary rocks should be carefully explored. In places the ores stand out in great black ridges, but elsewhere they are concealed beneath the debris that has slid down the mountain sides.

**Aluminum** in warm and boiling hot solutions containing hydrochloric and sulphuric acids evolves hydrogen with great rapidity, and reduces ferric salts to the ferrous condition, and its use for that purpose has been suggested by W. H. Seamon in the Western Chemist & Metallurgist. It is more than three times as active as zinc. Fifty-five parts of aluminum produce six parts of hydrogen, while 65 parts by weight of zinc yield but two parts of hydrogen. Theoretically, one part of aluminum should reduce six parts of iron, and the consumption of aluminum is very small, less than onetenth of a grain for ores carrying a high percentage of ferric iron. The reduction from sulphuric solutions is perfect, and more rapid than with zinc. By boiling for four or five minutes most ores will be completely reduced; if greater rapidity than this is desired, the addition of a few c.c. of hydrochloric acid will make it almost instantaneous. As a substitute for stannous chloride in the bichromate method its use will be found most satisfactory. In hot hydrochloric solutions the reducing action is as rapid as stannous chloride, and it is impossible to use an excess. The aluminum should be left in the solution while cooling down to the temperature of the room. When ready to titrate, pour the solution into a vessel and complete the titration, rinsing out the vessel in which the reduction was effected with tap water and completing the titration. The aluminum sheet now furnished for assayer’s use contains but 0.1% iron, corresponding to an error of about 0.02%, or less, when half a gram of pulp is employed.
MINING AND METALLURGICAL PATENTS.

Specially reported for the Mining and Scientific Press.

AMALGAMATOR.—No. 900,965. Fred Stringham, Monton, Colorado.

No. 900,965

No. 900,466

In an amalgamator, the combination of a pan adapted to contain an open bed of mercury, a block rising from the central portion of the pan and projecting above the surface of the mercury, a feed tube terminating slightly above the block for feeding the material, and mechanical means acting in the space between the tube and block for removing the material therefrom and delivering it laterally onto the open surface of the bed of mercury.

The method of treating ores, which consists in producing a molten bath high in fuel values, dissolving in the bath ores having constituents for releasing and fluxing the iron and mineral values contained in the molten bath, the process when started being carried out without the use of carbonaceous fuel and by the heat produced by the oxidation of the fuel values of the ore and bath, and during such process varying the area of the escape openings of the vessel in which the process is carried out conformably to the heat requirements of the bath, whereby the heat produced within the vessel may be held therein to a controllable maximum extent: substantially as described.

MEANS FOR PREVENTING MINE DISASTERS.—No. 903,492. Martin T. McDonough, Sun, West Virginia.

A mine having a main hauling way, auxiliary hauling ways and working passages, a manway or safety passage substantially parallel and co-extensive in length with the main hauling way, and means for creating a current of air through the auxiliary hauling ways and working pass-

gages, said current finding its outlet through the manway and the main hauling way.

A stamp mill tappet having a stem bore, and a channel at its side, the end walls of the channel being straight and joining the wall of the bore at points of the separation approximately but slightly less than the length of the diameter of the bore, whereby the stem may be wedged between said end walls, the wedging points on the stem being separated approximately but slightly less than the length of the diameter thereof.

Blast furnace charging apparatus, comprising stock carriers in which the materials are hoisted and charged into the furnace top, and mechanism arranged to distribute the contents and vary the relative location of coarse and fine materials in the successive carriers preparatory to hoisting them to the furnace top; substantially as described.

ORE-FEEDER.—No. 902,491. Alexander McCombie, Grass Valley, California.

In an ore feeder, the combination with a battery frame, of ears secured thereto, feeding mechanism including a conduit or spout, and angularly disposed sets of arms secured to the conduit or spout, the arms of each set being divergently disposed, said arms and ears being provided, one with sockets the other with pins, that detachably engage in the sockets.
COMPANY REPORTS.

ALASKA-TREADWELL.

The annual report covers the year ending May 31, 1908. The 540 stamps crushed 743,097 tons of ore, yielding $887,509 as free gold extracted by amalgamation and 12,963 tons of concentrate, giving by smelting at Tacoma an additional $736,636. Thus the yield from concentrate was nearly equal to that from amalgamation. The total yield was $1,624,145, as compared to $1,211,871 last year. The yield per ton was $2.18, as compared to $2.15 last year. The total operating costs were $577,493, showing a cost of $1.00 per ton and a profit of 64.5% on the gross production. The deepest level is at 1450 ft. The bulk of the output came from the stopes between 600 ft. and 1650 ft. From the pits 's glory hole' only 8,318 tons were taken. It is now no longer economical to break ore in these open workings, owing to the depth attained—a maximum of 500 ft. During the year 9764 ft. of development work was accomplished. The ore reserves are estimated at 4,664,743 tons, of which 709,055 lies broken in the stopes. Thus there is enough ore for 6 years, at the present rate of extraction. There are 32 machine-drills in the mine, averaging 35.9 ft. of drilling per 10-hr. shift, and breaking 29.33 tons per machine per shift. The maximum duty was 8.48 ft. drilled and 52.9 tons broken per shift. In the pits the average was 87.8 tons broken per drill at a cost of $3.12 per shift for explosives. The average cost of explosives in the mine was $2.86 and the average cost of supplies, power, and repairs was $3.72 per machine-shift. From 3482 samples taken in the mine the average yield was $5.45 per ton. The 240-stamp mill lost 17 days 20 hours during the year and crushed 277,271 tons, equal to a duty of 4.51 tons per stamp. The quicksilver used weighed 53,158 oz. Also 756 shoes and 400 dies. The 300-stamp mill lost 144 days 15 hours and crushed 365,826 tons, or 5.5 tons per stamp. Of quicksilver, 80,929 oz. were used; also 921 shoes and 500 dies. This mill is not operated in mid-winter. It was idle during February, March, April, and part of May. The cost of milling was 17.56 cents per ton. During the year crude oil replaced coal as fuel for making steam. The saving made amounted to $56,755; this was done at a total cost for equipment of only $28,678. Oil is now used exclusively in all the steam-power plants of the Company.

The report and the accounts are complete and detailed.

This is not only one of the big gold mines of the world and the one exhibiting lowest costs, but it is also one of the best managed in every department. Robert A. Kinzie is superintendent, E. P. Kennedy is assistant superintendent, and F. W. Bradley is consulting engineer.

NEVADA CONSOLIDATED COPPER.

Boston.—The Nevada Consolidated Copper Co. has issued its second annual report. The financial statement as of September 30, 1908, compares with that of June 30, 1907, as follows:

*Includes stock of other companies, including Stumptoe Valley Smelting & Mining Co., Nevada Northern Co., and Cumberland & Ely Copper Co.

The Nevada Consolidated issues a statement of condition of the property and work thereon since November 4, 1907.

Pope Yeatman, consulting engineer, recommends that another unit be added to the concentrator for handling Nevada Consolidated ores. Prospecting on the Eureka section has developed over 5,000,000 tons of ore of an average grade. This increased ore blocked out to fully 20,000,000 tons.

Ore blocked out represents an area small in proportion to the total, and possibilities for a large increase of tonnage are very great, not only through considerable extension of present workings but also in new areas which have not yet been reached, which give similar indications of promise to those shown in the developed area. Up to November 1, 185,277 tons sulphide ore have been mined. Total yardage up to Nov. 1 for stripping is 427,344. The sixth section of the concentrator will be placed in commission in December. The capacity of the plant has been increased from 250,000 tons to 500,000 tons.

Considerable work has been done on water rights during the past year, and a pipe-line has been completed and is in operation, furnishing ample water for present smelting operations, boiler purposes, and for concentration, up to date, even without re-pumping of tailing water, and, in addition, there is ample for a plant many times the size of the one in operation.

James Philpitts, Jr., the president, says it is confidently expected that construction of the additional unit, the fifth of the series, will raise annual production of blister copper to approximately 70,000,000 lb. From data at hand, it may be accepted with confidence that in January 1909 monthly production will be equivalent to an annual production of at least 35,000,000 lb., and that by April next, when additional concentration and smelting plant under way are completed, increased facilities will result in raising annual output to 50,000,000 or 55,000,000 lb. Should Mr. Yeatman's recommendation that still another unit be added meet with favorable consideration reasonably to be expected of the incoming board, it is well within probability that by September next this Company will take its place as one of the six largest copper-producing companies of the world.
Suction Gas-Producer Plants.

Producer gas has been rapidly replacing steam as a source of power for large plants, and it is even invading the field in competition with steam in small units. At a mine in the State of San Luis Potosi, Mexico, a 30 hp. gas-producer supplying gas to a hoisting engine, has been in service for over a year, using charcoal as fuel. This plant shows a consumption of only 1 lb. charcoal per horse-power hour, and the total cost for power amount to 53 per diem of 16 hours. The apparatus used is the suction gas producer made by Fairbanks, Morse & Co., of Chicago. This is illustrated in the accompanying cut. The fuel is introduced to the producer through a hopper at the top. This has a double closure, so that fuel can be admitted without at the same time admitting air. In the process of partial combustion which takes place, producer gas is generated, that is, the fuel is burned to carbon monoxide (CO) with the insufficient supply of oxygen. The hot gas passes through a vaporizer, in which a small amount of steam is formed, which, with a limited amount of air, passes under the grate of the producer. In the smaller sizes, the vaporizer is at the top of the producer, where it uses the waste heat from the escaping gas, and at the same time the water keeps the top from getting too hot. In the larger sizes the vaporizer is separate and connected to the producer by piping. From the vaporizer the hot gas flows through the scrubber, which is a cylindrical tank filled with coke, over which a spray of water is constantly sprinkled. The large contact-surface presented by the coke effectively cleanses the gas of dust and impurities carried over from the producer, and also serves to cool the gas, which is essential in order to prepare it for use in the engine.

With certain fuels, especially when much tar is formed, it is also necessary to add a sawdust purifier, in order to abstract the last traces of tar from the gas. While not absolutely essential, it is always advisable to use a gas tank between the scrubber and the engine, in which a certain amount of gas is stored.

The principal attention required by the producer is that of poking the fire every few hours when using coal, in order to break up and remove clinkers which would otherwise interfere with making sufficient gas. Poke-holes are provided so that every part of the fire can be reached conveniently. Anthracite in 'buckwheat' or 'pea' size, lignite, coke, and charcoal are the fuels commonly used. The lignite producer offers a cheap and reliable power in districts where this fuel is available. There are enormous deposits of lignite in Texas, Arkansas, Louisiana, North Dakota, Montana, Wyoming, Colorado, and other Western States. This can usually be had at from $1 to $3 per ton. At Smithville, Texas, where a 150-hp. lignite producer plant is installed, the cost is $1.75 per ton.

The Fairbanks-Morse multi-cylinder vertical engine is a mechanism of extraordinary efficiency. The features meriting special notice are the following: The present system of ignition is a great improvement. The make-and-break igniter is so constructed that it can be adjusted to spark as early or as late as desired, when the engine is running or at rest, by means of a convenient hand lever. A single lever controls the time of ignition for all cylinders. This is a feature of much importance, especially with producer gas, as it permits timing the ignition to give the greatest possible power and economy with any particular grade of gas and when the engine is running. In addition, there is an independent adjustment for each igniter which is operated by drop cam. The igniters can be removed, inspected, and cleaned without interfering with other working parts, and they are placed most conveniently. As the successful operation of a gas-engine depends largely upon the igniter, the value of these features cannot be emphasized too strongly. Both valves are operated from a single cam-shaft inside the crank-case. This minimizes the amount of noise. The simple fly-ball governor operates a balanced disk-valve so constructed that there is no frictional contact to become fouled by impurities in the gas. This is especially important with engines operating on producer gas. Lubrication is effected by a single elevated oil reservoir, provided with separate brass pipe with individual sight feed for each bearing. The drip from the different bearings collects in the base of the engine, which is drained by means of a small pump. Each engine is fitted with a hand-operated speed-regulator, by means of which the speed can be reduced when engine is running. One cylinder of each engine is fitted with automatic compressed-air starting gear. This can be thrown into or out of action by the movement of a single lever, and the engine is started automatically on compressed air.
**Decisions Relating to Mining.**

Specially reported for the Mining and Scientific Press.

**IMPROVEMENTS ON CONTIGUOUS CLAIMS.**

Under the United States statutes requiring the making of improvements on each mining claim each year, except where claims are held in common, then the improvements may be made on any one claim only where two or more claims are contiguous and are held in common.

What may be considered "improvement" of mining claims.

The value of the following articles may be considered in estimating the value of improvements on a mining claim: powder, fuse, and candles; the reasonable value of meals furnished, laborers employed in doing development work, who received board in addition to their wages; but not sums paid for transporting such supplies. The value of rails laid on ties in a tunnel, and a reasonable value for the deterioration of tools, may be considered, but not the price paid for such tools. Nor do such items as cutlery, dishes, tinfoil, provision, tobacco, and bed-clothing constitute improvements. The location is entitled to a credit for the actual work of an employee, though hired as a watchman, where no watchman was required.

**MINING LEASE—TRUST FUNDS—SET-OFF.**

A lessee in a mining lease having in its bands certain trust funds belonging to the lessee as the proceeds of the sale of ore under the terms of the lease, cannot retain such funds in order that it may offset against the same damages due for violations of the lease.

Florence-Goldfield Mining Co. v. District Court of First Judicial District of Nevada, (Nev.) 97 Pac. 49. (No date.)

**MINING LEASE—FUNDS IN LESSOR'S POSSESSION—DEPOSIT.**

The lessee under a mining lease was to deliver all ore to the lessor, who should mill the same and pay to the lessee a certain per cent of the smelter returns. In an action by the lessee against the lessee for damages for violating the terms of the lease, the lessee admitted the possession of a sum due the lessee; it was held that the lessee was the trustee for the lessee as to such sum, and was properly directed to pay the same into court.

Florence-Goldfield Mining Co. v. District Court of First Judicial District of Nevada, (Nev.) 97 Pac. 49. (No date.)

**PLACER CLAIM—EXCESSIVE AREA.**

The fact that a placer mining claim as stated exceeded the legal limit had the effect to render the claim void only as to the excess; and where the owner was in possession and working the claim in good faith, he had the right to elect what part he would relinquish as such excess within a reasonable time after he discovered such fact, and he could not be forced to surrender any particular part by the location thereon of an overlapping claim by another before he knew of such excess.

Zimmerman v. Fuchion, 161 Fed. 859, May, '03.

**POSSESSION OF MINING CLAIM—TEMPORARY SUSPENSION OF WORK.**

Where locators, after properly locating a mining claim and marking its boundaries, had sunk a shaft resulting in the discovery of mineral, a temporary suspension of work for a few days to procure tools and supplies for continuation did not constitute a break in the actual possession sufficient to entitle another to enter upon and re-locate any portion of the claim, although such entry was made before the locators had actually discovered mineral.

Hanson v. Craig, 161 Fed. 841, May, '03.

**Publications Received.**

Any of the books reviewed or mentioned in these columns are for sale or procurable from the Mining and Scientific Press.

This little book is intended not only for students of various sciences, but "the whole of those people who, though proud of the local commercial position of this country (Great Britain), are unaware as to how greatly this is due to our coal supplies. It discusses especially the origin, position, and extent of the seams, and the economical utilization and application of coal. Its main usefulness will evidently be to the general reader. For student purposes it is too brief and general, and it is not always exact, namely, in the statement, p. 39, 'Most geologists agree that 'Cannel' coal is of marine origin.' The geological portion is not inclusively written, and the paleontologist and paleobotanic text seems over-elaborate for a general reader. The notes on the coalfields outside Great Britain are brief, and there are few references to sources. The statistics of American production are for 1892. The best chapters are those relating to the use of coal, such interesting tables that (p. 170) "In the cases of the applications of coal, have nothing to show how they are derived and on what authority they rest. Analyses are quoted and compared without any discussion or statement as to how or on what basis they were made. Many evidently represent air-dried coal, but some, pp. 158, 162, etc., seemingly have been calculated to a no-moisture basis. Until the methods of sampling and analysis are at least stated, there is not much benefit in comparisons of coal analyses.

In brief, concise form, instructions are given in this little volume for making all the standard tests of cement required by modern engineering practice. The ingredients of the cement and the applications of cement have nothing to show how they are derived and on what authority they rest. Analyses are quoted and compared without any discussion or statement as to how or on what basis they were made. Many evidently represent air-dried coal, but some, pp. 158, 162, etc., seemingly have been calculated to a no-moisture basis. Until the methods of sampling and analysis are at least stated, there is not much benefit in comparisons of coal analyses.

This volume is, in a nature, a companion piece to the previous volume on 'Sewer Design' by the same author. Both are based upon a series of lectures given in the College of Civil Engineering at Cornell University. This volume is an exceedingly valuable one, and should be of great use to designers, contractors, and inspectors of sewer work. The illustrations are numerous and of the kind that illustrate. An especially valuable feature of the book is the example of a contract and specifications, with a detailed discussion of the various clauses. Numerous examples of particular work and cost data are included.

Beginning with the anatomy and physiology, the book succinctly deals with germs or micro-organisms; first aid materials; general directions for rendering first aid; shock; common accidents and injuries; common emergencies; occupation accidents and injuries; injuries and emergencies of indoor and outdoor sports; transportation of wounded and sick; organizations for first aid instruction; first aid contests; closing with a list of references and a complete index.
EDITORIAL.

DECEMBER disbursements of dividends recorded at New York will exceed $105,000,000, as against $86,054,000 a year ago. The total for the year will be $1,243,334,327. This is evidence of a return of prosperity.

BY THE PAYMENT of the recent $5 dividend the Calumet & Hecla has now paid $107,850,000 to its shareholders. Current production is at the rate of $5,000,000 pounds of copper per year, at a cost of 8½ cents per pound, so that 15-cent copper leaves a handsome margin.

FROM the Secretary of the Transvaal Chamber of Mines we learn that the output of gold in the Transvaal in October was 617,744 fine ounces, worth $2,624,012, or $72,726,460. This constitutes a record, for it is 29,931 ounces more than the previous highest output.

ANNOUNCEMENT is made that the gold medal of the Institution of Mining and Metallurgy has been awarded this year to Mr. James Douglas, "in recognition of his services in the advancement of the educational, technical, and commercial interests of mining and metallurgy, and of his important contributions to technical literature." This is an honor most worthily bestowed, and will give keen pleasure to the many friends of Mr. Douglas. By awarding the medal to such a man, the Institution adds greatly to the value of the medal.

THE PROJECT of mining-law revision as presented to the Mexican Congress by the Minister of Pomento, Sr. Olegario Molina, would restrain foreign corporations from 'denouncing', that is, locating, and from owning mineral lands within a zone 80 kilometres (51.2 miles) wide along international frontiers. Individuals may denounce and acquire title to lands within these zones only through permission granted by the President. Special permits for exclusive right to prospect within zones in which minerals may have been discovered, have not been productive of beneficial results, and they will no longer be issued. By the new law, which is to become effective July 1, 1909, property in mines will be subject to the Civil Code where not in contravention of the specific provisions of the mining law itself.

ORE IN SIGHT usually refers to a mass no more definite than that seen on a foggy morning, when looking up at the under side of the gloom an observer might remark: "Clouds in sight." Indeed, to press the simile further, when the miner asserts that so many tons of ore are 'in sight', there are invariably deep cloudy recesses that he has not pene-
treated, imperiling the accuracy of his arithmetic. Ore in sight is not definitive, because it is susceptible of varying interpretations. As an example of a correct use of the phrase, however, we call attention to the statement in our news from Rossland this week that "there is a good body of ore in sight on the 1650-ft. level." In other words, the indications are good, though indefinite. When speaking of ore in measured quantity, the term 'blocked' is incapable of being twisted into false meanings; even better is 'ore ready for stoping'.

TARIFF REFORM is in the air. The most significant incident of late has been the frank statement by Mr. Andrew Carnegie, in a magazine article, that steel can be made in America "cheaper than anywhere else, notwithstanding the higher wages paid per man." He adds: "Not a ton of steel is produced in the world at as small an outlay for labor as in our own country." Finally: "The day is past when any foreign country can seriously affect our steel manufacturers, tariff or no tariff." It must be confessed that Mr. Carnegie's testimony on this subject is worth more than his opinion on reformed spelling and sundry other questions on which he has been quoted as an authority. He is the most notable of the men who have made a vast fortune by shrewdness, railroad rebates, and the tariff. As the holder of $300,000,000 worth of 5% bonds of the Steel Corporation, he has a property interest in the steel business of America such as gives extraordinary weight to his dictum. Evidently he believes that the removal of the tariff on steel will not hurt the American industry nor, incidentally, his share of it. His frank statement has already disgusted those who look upon him as one of the prime beneficiaries of protection, and the New York Tribune upbraids him for "tearing down the walls which enabled him to amass wealth." It is amusing and it is instructive.

OLD has been obtained for centuries from the Province of Sandia, Peru. We publish an interesting article this week by W. E. Gordon Firebrace describing the placer deposits now being exploited at San Antonio de Poto, in that Province. Being on the west side of the middle Cordillera of the Andes, there has been difficulty to secure a cheap water-supply. This trouble has now been overcome and successful hydraulic mining at Poto seems assured. The great Cordillera is made up of schists with innumerable gold-bearing veins and veinlets, strikingly similar to the California gold-belt, and to the Seward Peninsula in Alaska. The District of Sandia on both sides of this range contains a long succession of auriferous gravel-beds, which in the vicinity of Carabay have been eroded, leaving extensive gravel ridges several hundred feet in height. The stream concentration following this erosion is supposed to have furnished the bulk of the gold accumulated by the Incas. These people had even attacked the low-grade gravel hills, and removed material aggregating millions of enbie yards. The length of time during which these deposits were worked by the Incas must have been enormous. The region well merits the attention of the modern miner whose skill and economy may find in Sandia a favorable opportunity for successful application.

Bureau of Mines.

On another page we publish a thoughtful letter discussing some features of the proposed National Bureau of Mines. The letter is from Mr. H. Foster Bain, State Geologist of Illinois and a mining engineer of high rank. He is particularly well qualified to express opinions and to make suggestions in the matter, because he has taken a prominent part in the promotion of the Bureau at Washington. A bill passed the House, and, after a favorable report from the Senate Committee on Mines and Mining, it awaits the approval of the Senate. Meanwhile, the Director of the Geological Survey has suggested that this new bureau be called a Bureau of Mining Technology, so as not to trespass on the province of the Survey. Mr. George Otis Smith says that "geologic studies form the foundation of the mining industry", and therefore the word 'mining' by itself is inappropriate for a bureau that would conduct only a part of the investigations that relate to mines and mining." We wish that it might be said without cavil that geologic study is at the foundation of mining as now practised; it ought to be, but it is not: the pick and shovel, aided by muscle, and then by steam, constitute the fundamentals of mining, and that is exactly why the Geological Survey is deemed an inadequate guide to the safe conduct of an industry in which human life is risked and complex business interests involved. Naturally, the Director and his coadjutors are anxious to conserve the prerogatives of the Survey, and our readers, all of whom must necessarily be highly appreciative of the work that has been done, and is being done, by the Geological Survey, will hope that the new bureau can be established without injury to the one already in existence; nevertheless, the problems coming within the scope of the proposed bureau are so diverse and important that its administration will not likely be subordinated to that of the Survey. Frankly, this not unnatural jealousy, already imminent between the two bureaus, had best be overcome by placing them on an equal footing under a strong chief. The Geological Survey and the Mining Bureau ought to be under the Secretary of Commerce and Labor, for it is obvious that he is the officer of the Federal Government in closest touch with industrial conditions. The Survey would gain by being more strictly devoted to the purpose for which it was founded, and from which it has departed in statistical and hydrographic excursions that have dimmed a reputation for scientific work of the very first class. We know that some of its statistics are not as reliable as some of those collected by private enterprise; this is a great pity. The fuel investigations have yielded insignificant scientific and practical data, and have not advanced the state of the art in fuel economy. We do not impugn the devotion to duty nor question the scientific training of the gentlemen in charge of this work, but they are not fitted by previous experience to perform
the office of technical leadership. In the hands of a man like Mr. William Kent the work would have yielded results important to the scientist and to everyone interested in the industrial application of fuel-energy. The Bureau, on the other hand, should facilitate the systematic investigation of mining and metallurgical problems without trespassing on industrial initiative; it should co-operate with the State governments in ascertaining the causes of mine accidents; it should have charge of statistical work, in friendly co-operation with the geologists of the Survey.

Whether the Bureau should conduct experiments in practical problems of mining, ore-dressing, and metallurgy is open to question. The tendency of such concentration of experimental studies into the hands of a few would be to discourage investigation by the many, and to limit scientific progress to narrow grooves. By giving undue prominence and authority to the work of a small corps of experimenters, no matter how great may be their talent, the broader ends of scientific progress are not attained. The Agricultural Department has avoided this pitfall, and doubtless a Mining Bureau could follow the trail blazed by the guardian of this other field of primal wealth. But the co-operation of State experimental stations is not necessarily the best, nor even the sufficient, means for carrying out this particular phase of paternalism in government. Many colleges and universities possess equipment in men and laboratories that under special arrangement could be utilized, thus supplementing the financial ability of the universities to conduct valuable investigations. Such work, moreover, being done in institutions of learning, would immediately enlist the interest of students; this in the aggregate would immensely further the dissemination of new knowledge, and stimulate fresh research to a degree unattainable through the mere distribution of bulletins.

We do not believe that the Agricultural Department has elaborated the most efficient plan. The Mining Bureau could do better. Certain it is that investigations of this kind should be conducted in such a way as to receive impetus and direction from local needs in every part of the country. The tendency of any Bureau is to fall under the influence of a few special industries, and of a few important operators. This tendency is enhanced when the activities of the Bureau are concentrated at one place. We believe that in Canada it has been customary for the Provincial governments to entrust scientific investigations to specially competent men in the universities, without regard to political or other bias. From this we may take a hint. It is better than a commission, which is prone to find in the work an occasion for diversion in a holiday jaunt; it is better than the routine performance of men who may by mere good fortune happen to be the best ones to conduct the investigation with enthusiasm and ability. Moreover, the college professor is more likely to take a scrupulously conscientious view of moral responsibility toward the people than one who has a tender regard for the continuance of a salary from the public coffers—save the mark!

A Mining Bureau has a particularly useful function to perform in opposing waste—not only profligate dissipation of natural resources, but waste of effort through ignorance and the easy drift along conventional channels. We are today taxing the people with an excessive tariff to make iron, while wealth is being flung into the air from flaming coke-ovens with a disdain of future needs that will make us seem crude barbarians in the eyes of our descendants. The Bureau would find large opportunity for proving its right to exist by helping to rationalize industry in the conservation of mineral resources, which, once taken from the earth and used, are irreplaceable. We know that the leading technical and professional men in the West are taking a keen interest in this subject; we hope that they will express their opinions freely in the columns of this journal.

Dredging Consolidation.

Dredging in California is becoming increasingly important. A consolidation just effected emphasizes this importance by the largeness of the capitalization involved. The Natomas Consolidated of California is a corporation controlling 6000 acres of dredging land and operating 14 dredges; it is a consolidation of the Natoma Gold Dredging, Folsom Development, Feather River Development, El Dorado Gold Dredging, and Ashburton Mining companies; besides sundry additional tracts of dredging lands not owned by any previously formed company. The capitalization includes $25,000,000 in bonds and $25,000,000 in stock. The dredging portion of the enterprise supports half of this capitalization, the remainder covering reclamation of land, sale of water to Sacramento and its suburbs, and other allied enterprises. The president is Mr. Frank Griffin, who is to be succeeded shortly by Mr. E. J. De Sabla, Mr. Griffin becoming vice-president, together with Mr. Louis Sloss, of the Alaska Commercial Company. Mr. W. P. Hammon will be managing director, and will give his unique knowledge of dredging operations to the furtherance of this important enterprise. This places an enormous amount of dredging work under Mr. Hammon's direction, for he is general manager already of both the Oroville Dredging and the Yuba Consolidated. The latter is the largest gold dredging enterprise in the world, for it operates 12 dredges, produces over $1,600,000 per year, and pays $1,200,000 in dividends. We understand that the Natomas Consolidated expects to earn a profit of $900,000 to $1,000,000 in 1909 from the dredges, increasing this to $1,250,000 or $1,500,000 in 1910. The 6000 acres of dredging land are expected to give a life of 17 years to the undertaking. Three dredges are to be built shortly, the total number of machines increasing to 17. The ground to be worked is near Folsom, in Sacramento county, and near Oroville, in Butte county, California. The ground is estimated to average 10½ cents per cubic yard and the cost of dredging is expected to average 4 to 4½ cents per yard. Having regard to the marked revival of interest in this branch of the mining industry, we are glad to give our readers this information.
Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Arthur S. Earle is at Bath, England.

R. C. Shaw is now living at Berkeley, California.

Harold Rickard is now living at Zacatecas, Mexico.

Benham Hunt has returned to San Francisco from Alabama.

T. C. Scoutron has returned to London from the Malay States.

E. M. Hamilton is at the Dolores mine, in western Chihuahua, Mexico.

J. C. Brown has returned from Boston to Argentina, Kansas.

Edgar Rickard is making a flying trip to New York and Pittsburg.

James E. Johnson, of Los Angeles, was recently at Durango, Mexico.

Otto Suesmann has moved his office back to Salt Lake City, from Denver.

Wallace, Glove, & Summehates, of Nogales, have dissolved partnership.

H. Vincent Wallace is in Lower California, examining manganese deposits.

William M. Brewer has returned to Victoria from a trip to southeastern Alaska.

James Gayley has resigned as vice-president of the United States Steel Corporation.

Frank Proctor passed through San Francisco, on his way from Rawhide, Nevada, to Los Angeles.

Jasper Lindenbe for has returned to San Francisco from Nome, spending a few weeks at Seattle.

Frank A. Leach, Director of the Mint, came to San Francisco to give testimony in the Ruef case.

J. Nelson Neish, of Pasadena, has been investigating methods of dredging at Oroville, California.

T. S. Drummond becomes superintendent of the Newhouse mines, in Utah, relieving Lafayette Hanchett.

R. V. Norris, consulting engineer to the Stone Canyon Coal Co., has returned from California to New York.

Lewis T. Wright has returned to San Francisco from a trip to the iron and copper regions of Minnesota and Michigan.

J. B. Tyrell recently returned to Toronto from Sturgeon lake, in northern Ontario, where he examined several gold properties.

Chester A. Thomas, manager for the Yukon Gold Co., is at New York, and is expected shortly at Santa Barbara, California.

Charles W. Merrick has returned from Arizona, where he installed a precipitation plant for the Alvarado Mining Co., at Congress Junction.

E. J. Frank, of New York, is in San Francisco, on his return from Plumas county, where he is manager for the Indian Valley Mining Co., at Greenville.

William S. Mann, general manager for the Boston & Oakes Mining Co., has returned to Tacoma, in Oaxaca, Mexico, from a trip to the United States.

Obituary.

E. W. Chapman, resident manager of the Channel Mining Co., was killed in the Chapman mine, near San Andreas, on Sunday afternoon, November 23. The accident was due to a cave of gravel from the roof, in a raise from the main gangway about 150 ft. from the main shaft. Although death was probably instantaneous, Mr. Chapman’s body was not crushed when recovered after six hours of strenuous exertion by the men working in 20-minute relays. Mr. Chapman was a thorough-going miner, a captain under whom it was a privilege to work, and whose word was as good as his bond. He never asked his men to go where he would not go; pick in hand he put in his last shift.

Dividends.

On December 4 the Bunker Hill & Sullivan Mining & Concentrating Co, paid dividend No. 135, of $75,000. This makes the amount of dividends paid this year $855,000, and the total to date $19,671,000.

General Mining News.

ARIZONA.

COCHISE COUNTY.

It is said that Joe Larrienn, of Benson, and C. E. Rule, of Tucson, are also interested in a project to erect a concentrator at Paradise, and that a stock company will possibly be organized.—The Willie Rose Co. expects to resume operations in its property near Portal early in December and is asking for bids for sinking 50 ft. in its 27-t. shaft.

GRAHAM COUNTY.

The first carload of machinery for the New England & Clifton Copper Co.'s aerial tramway arrived at Clifton this week and will be transferred to the Copper King mine at once. Two more carloads of material are due in the near future, after which the local management will rush the installation. The new compressor, hoisting plant, and drilling machinery are now in operation and upon the completion of the aerial tram the Company will be in a position to greatly increase ore shipments and reduce the cost per ton.

MOHAVE COUNTY.

The Lyons Gas Co., of New York, has contracted for the purchase of a large acreage of turquoise land at Mineral Park. A representative of the Company was at the Park last week and took over the mines of John and Cordelia Kay, John Casswell, and John Gross, and is preparing a working arrangement with those owners. The Company purposes to handle the stones at its own laboratory in New York and the owners of the mines are to participate in the profits accruing from the product. They also get a good price for the mines and are to have charge of the respective properties.

YAVAPAI COUNTY.

Machinery is being installed at the property of the Black Mountain Copper Co., on the same hill near the east side of the Smelter Creek. The equipment includes a 150-hp. boiler, a 60-hp. hoist, a five-drill compressor, and a sinking pump. The shaft is now 125 ft. deep, but it will be sent down several hundred feet farther, cutting levels at each 100-ft. point.—The New York syndicate, which recently purchased the Elta mine, is putting up a 10-stamp mill and will later build a cyanide plant. The company is driving at the 180-ft. level of an old shaft and there is a large tonnage of ore exposed in the old stopes ready to be mined as soon as the mill is finished. The Elta is five miles west of the Verde river and 18 miles south of the United Verde mine at Jerome.—T. W. Wampler, who recently purchased the Peterson group of October, has cleaned out the lower adit, put the track in, and equipped the blacksmith shop. A contract for 100 ft. of driving is to be let for a trial. A trail of 100 ft. at a gradient of 10%, is being constructed from the old Johnson road to the mine. It will later be converted into a wagon road.—It is probable that the United Gold Co. will build a cyanide plant at its 4-stamp Nissen mill on the Alaska group near Congress. J. H. Morrison is master mechanic.

YUMA COUNTY.

An Indian mining syndicate has taken a lease on the Bell of Arizona mine, at Quartzite, and will treat the ore from the Virgin Queen mine. H. H. Lahr is manager.—A strike of $100 ore was recently made on the Ironwood claim in the Kofa district. The vein is 12 ft. wide and is only 1000 ft. from the well known Ready Money property. Frank Payne, of Kofa, has recently purchased the ironwood. —Ernest A. Haggott, of Los Angeles, has let the contract to the McEntee Bros. to sink a 100-ft. shaft on the south Cholla group of claims about 1½ miles south of Salome. The shaft is to be put down at a point about half a mile southeast of the Cholla shaft now down 40 ft.—The Harqua Hala Co, will, it is reported, build a cyanide plant to treat the old tailing. Barkey Quinn is in charge.—The Ultimatum group, 9½ miles from Salome on the north slope of the Harcuvar range east of Tank Pass, has been bonded to a group of Houghton, Michigan, men. Two shifts are at work sinking a shaft which will cut the vein at a depth of about 200 ft.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence.)—Sinking has commenced at the Rose Hill, and a winze is being put down from the south drift, where the vein is exposed.—After three years' continual endeavor the Idaho-Maryland Co. has watered the Idaho shaft to the 1600-ft. level. The old pumps on that level have been placed in fair condition and will start up for the first time in eight years within a few days. From this point the west drift will be extended to intersect the main vein. The mill has been placed in first-class condition and 20 stamps will soon be dropping. The bins are full of ore from the 8-st. vein on the 5000-ft. level, and Bray Wilkins, who is manager, is completing arrangements for developments on an enlarged scale.—Frank Colvin and associates are pushing exploration and development work on the Norambouga North Ex. claim. It is likely that a strong company will soon take over the property.—Honolulu capitalists have bonded the Grover & Murphy claim, adjoining the Mountaineer on the north. H. B. Gray has been appointed superintendent.—The Kenton mine has been taken over by a new company and will be extensively operated. T. R. Garnier is superintendent and considerable development work is to be done immediately.—The Baliklala smelter, at Ceram, is to be worked in after an enforced shut-down of several weeks. The tramway has been put into good working order, and the various weak points disclosed by the short run have been repaired so that there is now every probability of the plant's running continuously. A force of about 300 men is working at the two mines.

SHASTA COUNTY.

Charles W. Brown, representing a Los Angeles company, has taken a bond on the Uncle Sam group, near Forest, and is making arrangements to start work at once.—It is reported that Charles M. Root, of Sacramento, is preparing to build a five-stamp mill on his property near Gibsonville. The Reese Ravine mine will be worked all winter under the management of W. C. Oaks.—Excessive water in the shaft at Poker Flat has made the installation of a pump imperative and M. Duval is in San Francisco to procure it, and also a drill.—The Brush Creek and Ante-Up quartz mines have been bonded by F. L. Cole and Frank R. Wehe to L. L. Battey of St. Louis, who will reopen the long cross-cut adit in the Ante-Up and extend the drift to the western edge of the Brush Creek mine. L. A. Armstrong, formerly with the Elko Consolidated at Cripple Creek, will have charge of operations.

TOLUCA COUNTY.

A new air-compressor has been put in at the Riverside, above Columbia. A large quantity of water-pipe was delivered at the mine last week.—Operations have ceased for the winter at the Grant mine, near Italian Bar.—An 18-hp. gasoline engine has recently been put in at the Ethel mine, near Big Oak Flat.—The Nerly Gold Mining Co. filed articles of incorporation in the office of the county clerk last week. Capital is listed at $50,000 and shares are $1 each. The directors are M. A. Colby, Los Angeles: J. B. Berzon, J. W. Bennett, F. M. Colby, K. M. Nealon, San Francisco. Columbia is the principal place of business.
COLORADO.
CHAFFEE COUNTY.

A strike of rich ore was recently made in the Banker adit at Winfield, in Clear Creek gulch. The vein is 5 ft. wide and is said to assay 8 oz. gold, 37 oz. silver, 9% lead, and 34% copper. The property is owned by a company of Allentown and Philadelphia people. Plans for sinking a three-compartment shaft are being considered and one firm has already had an engineer make a complete estimate.

CLEAR CREEK COUNTY.

(Special Correspondence).—Some time during December work is to be resumed upon the holdings of the Democrat Mtn., M. M. T. & D. Co. It is reported that the bond issue of $100,000 has been placed and that the Kelly adit, now in 2800 ft., will be driven ahead for the intersecting of the series of veins controlled. Work will also be carried on in the Kelso adit, the portal of which is 700 ft. farther up the hill. Driving is to be started on the Boston vein, where large reserves of milling ore are showing. F. Brownley is superintendent.—Shortly after the first of the year work is to be resumed on the East Griffith mine, on Griffith Mtn. The 50-ton mill will be started and driving and sinking will be carried on. A new company is now in process of organization and it is understood that ample funds will be available for the carrying out of all plans to a successful issue. The report was recently made by an expert, who estimates that there is blocked and ready for extraction $1,000,000 in silver-lead ore. W. D. Hoover, of Denver, is manager.—Work will be resumed next week on the Sporting Times mine, Alpine Mtn. The drift is to be continued for about 300 ft. to permit of putting through a raise to connect with the old shaft workings. A. H. Colburn is owner.—A force of 40 men is now being employed at the Wilcox and Tolson adits by the Waldorf Metals Co. The Wilcox bore is being driven ahead, and is now into the hill over 5200 ft. What is believed to be the Paymaster vein was intersected during the last week, a streak of heavy lead ore being uncovered that is from 18 in. to 2 ft. wide. Assays show more than $100 in silver and lead. D. F. Sprouse, the manager, states that the adit will be driven for at least 400 ft. farther, as two veins will be intersected that are held under lease. During the coming month electric power will be turned on to the transmission line running to the Tolson adit, after which Shaw stoping drills will be brought into use.—Within the next week the working force at the Terrible mine, Brown Mtn., will be increased to at least 40 men. The preliminary work now under way is progressing satisfactorily and within the near future driving will be started shortly from the eleventh, twelfth, thirteenth, and fourteenth levels. Heavy shipments are being maintained by the various lessees at work on the fourteenth level, contents averaging $100 per ton in silver and lead. B. C. Cattrin is manager.—The Josephine property on Kelso Mtn. is making a fine showing. J. R. Sapp, the manager, is employing a force of men in carrying a stope, as well as in driving the adit, which is now in approximately 1000 ft. —The Conqueror M. & M. Co., operating on Covelo Mtn., has entered into contract with the Two American Sisters M. M. P. & E. Co. for the furnishing of 100 hp. from the electric plant, two miles below Georgetown. Machine-drills have been ordered and the equipment will arrive during the coming month. The same Company is running a transmission line into the town of Empire and electricity will be sold to the residents of that place, as well as to a number of operating mines. J. W. White, manager, states that the lease in the Empire district is that operated by A. Thomas below the sixth level of the Gold Dirt. Stoping is in progress upon a body of ore that is from two to four feet wide and average returns of six ounces gold are being received. A force of from 15 to 20 miners is employed. Jacob & Horstem, leasing on the third level, have a body of ore that is from 15 in. to 2 ft. wide, and returns five ounces gold. Sixteen sets of leasers are at work in the various parts of the mine and the output for the present year will be heavier than at any time during the history of operations.—The Laneva M. Co. is employing a force of men in the advance of the U. S. adit, which is situated on Chicago Mtn. Driving is in progress upon several veins that have been intersected, chief among which are the Washington, Crosscut, Harrison, and Ohio. E. R. Fitzgerald, of Idaho Springs, is manager.—Fred Nye, manager for the Banner Con. M. Co., states that work will be started at once through the Centurion adit. Driving will be started upon the Centurion vein and the Rockford adit is being driven ahead, ground being broken at the rate of from five to six feet each day.—The transformer station for the Central Colorado Power Co., at Idaho Springs, is nearing completion and shortly after the first of the coming year electricity will be furnished throughout the counties of Clear Creek and Gilpin. The United Hydro Co., of Georgetown, has contracted for 4000 hp. and will be the distributing agent. Already a number of contracts have been made with large operators.

GEOGRAPHICAL REVIEW.

It is reported that a good strike has been made on the Rockford property in Russell district, which has recently been started by Sherman T. Harris and associates. The property is almost under the dump of the Topeta mine, and a wagon has been put up for temporary purposes. The strike is at a depth of about 75 ft., and the work is 1/2 ft. of smelting and milling ore in sight.—The Frank Augustus Mining Co. last week took over the tungsten properties on Beaver creek, two miles north of Rollinsville, known as the Tanner & Dunn and Wilson & Ogilvie groups, the consideration being $50,000, on which a substantial cash payment was made, the rest to be paid within 60 days. About 25 men are at work on the property and this force will soon be doubled. Arrangements are being made for electric power from the Eastern Colorado Co. to operate the compressor and hoist, and early next year a large concentrating mill will be built. From three to six cars of ore per week are being shipped.—Chamberlain & Co. have taken a contract for driving the 150-ft. level below the adit of the Mabel property at the junction of Russell and Willis gulches. The contractors have also taken a lease and during the past month shipped one lot of smelting ore which gave them net returns of $40 per ton. The property is owned and operated by the Vigilant G. M. & M. Co., in which Denver and Eastern capital is interested.—The Jefferson M. & M. Co. has taken a lease and bond on the Rails County group of three claims on Quarts hill, which is owned by Charles Gage, of Columbus, Ohio. Pennsylvania capital is chiefly interested in the new operations and the management of the property has been placed in the hands of J. F. Shaw. There is a modern plant of machinery and shaft building over the main shaft, which is down 700 ft., and operations have been commenced in the 300-ft. level.
LAKE COUNTY.

Work has started on the A. H. & Minnie property in California Gulch. It will require a month or six weeks to get the shaft and workings in shape to start mining. T. A. Monahan is superintendent.—Plots are under way for a smelter on the Huckleberry property in the St. Kevin district. This mine was closed a short time ago for repairs and a readjustment of its lease. An excellent streak of gold ore was being worked at the time the property shut down. The Leadville Light & Power Co. is making electrical connections with the property of the B. P. Mining Co., on Rock Hill, which has taken a lease on the Buffalo, President, Comstock, and other valuable claims in that district. The company is financed and managed by a concern of Eastern mining men who will exploit the property which they now control. A plant of the latest and most improved machinery is to be installed.

IDAHO.

BONNER COUNTY.

C. C. Titus, superintendent of the new Panhandle smelter at Ponderay, has returned from an ore-buying trip in the Coeur d'Alene. He is now looking for additional contracts to supply the second furnace, which is to be blown in not later than January 1. The smelter will have a large amount of ore from northeastern Washington, in which a large number of properties are ready to ship. None has yet come from the Metaline district, on account of the difficulty and expense attached to handling it several times, due to mixed river and railway transportation. One of the new roasters has been put in use and the third is nearing completion. The plant is handling from 115 to 135 tons of ore per day, most of it coming from Idaho and Montana. It is expected that shipments from the last-named state will be increased next month. The management is preparing to ship two cars of bullion to the refinery at Carnegie, Pennsylvania.—The Chihuahua group of claims has been sold for a consideration of $60,000. A syndicate of Eastern capitalists has purchased the group from J. H. McDonald, of Rosslind. Surveyors are now employed at the property in deciding on the nearest and most feasible route for transportation.

SHOSHONE COUNTY.

(Special Correspondence)—The question of the tariff on lead still continues to occupy the lime-light in connection with the mining industry of Shoshone county. A second delegation, consisting of W. Clayton Miller, C. W. Beale, Harry L. Day, James F. McCarthy, and Frederick Burbridge, has gone to Washington in the interests of the lead tariff. This committee, which represents the prime mining interests of the district, will work in co-operation with the delegation of business men already sent to Washington. H. F. Samuels, the pioneer of the zinc industry of the Coeur d'Alene, has also gone and will join with the Missourians in their fight for a zinc tariff.—The Hecla Mining Co. has declared its regular monthly dividend of two cents per share, involving the distribution of $29,000. This is the sixty-fourth dividend declared by the company, making a total of $976,000. The grand total is $1,650,000.—The Alice mine, on which a splendid strike of ore was made some time ago, will, it is reported, erect a concentrator next spring. The present needs of the mine will be met by the erection of store-houses. The principal owners of the mine are Wilson & Mackay, of Portland.—The first shipment of ore from the property of the Caledonia Mining Co. will probably be made in the course of the next ten days, and if the results are satisfactory shipments will be continued at regular intervals. The property is regarded as one of the most promising in the district and is equipped with everything but a concentrator. C. Fred Kratzer and Charles McKinnis, of Wallace, are the principal owners.—John Huerter and T. A. Paterson, of Spokan, have been appointed a committee on the erection of a smelter in Ponderay, on behalf of a syndicate of Spokane capitalists, with a view toward taking over the property. The men expressed themselves as well satisfied with the outlook, and if the deal goes through it is the intention of the new owners to equip the mine with a full line of machinery, including a concentrator, furnaces, a smelter, and water-power.—A 50-ft. contract, carrying a bonus of $1000 if ore is struck within the next 25 ft., has been let to Philip Goggins on the O'Peech property, on Nine Mile. This work will be devoted to an extension of the adit, which has already been driven about 450 ft. Some good ore has been opened up and two cars have been taken out and are awaiting shipment. The principal owners are Patrick Brady, Louis Sherrier, and William Goggins, of Wallace. The New York group of claims in the Delta district has been bonded to a syndicate of New York capitalists. The property was originally owned by the Wake Up Jim Mining Co. It is the intention of the New York people to erect a stamp-mill and operate the property on an extensive scale. Under the old ownership several shipments were made, in which the ore netted about $70 per ton. The principal owners are Jerry Savage, Frank Gauthier, and W. A. Ulick, all of Delta, Idaho.—There is a report current in Wallace to the effect that F. W. Isham, a promoter of Spokane, has bonded the Penny group of claims and will erect a stamp-mill after the first of the year. The group is about three miles north of Delta and is owned by the Ward brothers of that town. There is a large quantity of gold-ore ore on the dump waiting treatment.—One after another complications appear to arise in connection with the affairs of the ill-fated Anamor Mining Co. Last week the feature in connection with that mine was the discovery of a large ore-shoot carrying from 3 to 3½% copper, the existence of which had been concealed by plastering with a layer of dust. This week comes the report that the stockholders committee has met in Chicago and passed resolutions denouncing the directors of the company, and at the same time arrived at a decision to refuse to pay the assessment recently levied and carry the matter into court if necessary. The meeting is said to have been attended by about 200 stockholders, representing 500,000 shares of stock. The report of this meeting comes as a sort of blow to local holders, it was felt in Wallace that the assessments would go far toward doing away with many of the present complications and that the management would be able to start both the mine and smelter at full blast in the near future. If, however, the company is to be plunged once more into litigation and the assessments remain unpaid the outlook is almost hopeless. Wallace, November 28.

NEVADA.

ESMERALDA COUNTY.

The lease formerly known as the Chicago Florence is being actively developed by the Nevada Florence Co., its present owner. The company is now in a position to start its development, a situation is being cut. Henry Bell is general manager.—An ore-shoot 6 ft. wide has been opened at the north end of the Mohawk Ledge block, on the 300-ft. level. Shipments are now being made, one 45-ton lot having been sent out. The find is believed to be an extension of the Shees-lish-Kaltus vein. Richard Fitzgerald, the superintendent, expects to make of the lease a regular shipper.—A. D. Parker, of the Goldfield Placer Co., the great company that holds the property, will grant no more leases. The mill is nearing completion and the concern will mine and treat its own ore.—The Goldfield Brokerage Co. has secured a two years' lease on the Red Top Extension and has organized the Red Top Mining & Leasing Co. to work the property. The property leased is the Bulldog claim, a fraction almost completely surrounded by the units of the Goldfield Consolidated. The shaft, which is now down 250 ft., will be sunk to a depth of 600 ft.—W. J. Craig, general manager for the Red Metals Mining Co., operating near Walker lake, announces that his company will thoroughly develop its property, and from the strong surface indications hopes to make a big producer of copper within a short time. The Great Western, at Homerville, is now shipping to the Belmont mill at the rate of about 250 tons per month, and this will be materially increased in the near future.—It is still impossible to obtain production figures from either the producers
The Hero Nevada Mining Co., owning the Wildcat and Little Hero property, northwest of Farrell, upon which the remarkable discoveries of the last few weeks were made, has decided to make a mill run of its available ore at the Harris Damarest mill as soon as the latter is ready for action. The Maxuna Consolidated Mill & Leasing Co., operating the Prior-Chadbourne lease on Maxuna hill, have cut the Reagan vein in the west cross-cut from the 250-ft. shaft.

**HUMBOLDT COUNTY.**

The Round Mountain Mining Co. has declared another dividend of 4 cents per share. It is payable December 18 to shareholders of record on December 15. The mine and mill are producing heavily and there is every assurance that the present rate of dividend will be continued indefinitely. The Crown Point Globe Mining Co. declared a dividend on November 24 of one cent per share, payable December 20. The transfer books close at Johnnie, Nevada, December 15. The Chapman mill, at Manhattan, a sale of which has been pending for several weeks, has been sold through Chris McCarty. The purchasers agree to pay 40% of its indebtedness now and the remainder in six months. The mill consists of Huntington's, with cyanide and concentration. It treats 50 to 60 tons per day. The shipments from the mines of Tonopah for the week ending November 28 amounted to a total of 5387 tons, of an estimated value of $194,675.

**NEW YORK.**

Messrs. Behrend and Kidney, engineers of the Behrend Dry Concentrator Co., are examining the Grant mine at Carmel, in Putnam county, preparatory to erection of a concentrating mill of 50 tons capacity, under the Behrend dry system. The ore is complex in character, composed of sulphides and arsenates of iron, carrying copper, gold, silver, and nickel. On completion of the concentrating mill it is proposed to install a metallurgical plant for the recovery and separation of the arsenic and metals contained, by a new process. The crude ore has a gross value of $35 per ton, but on account of its refractory nature has at present no commercial value. The economic system evolved for the treatment affords means for highly profitable operation.

**WASHINGTON.**

(Land and Water).—Shipments of ore from the Lucille Dreyfus mine at Danville have been discontinued and two shifts of men are sinking the winze to a depth of 450 ft. Several shipments were made to the Northport smelter and gave returns of $8 in gold and copper. The property is owned principally by William R. Ridpath, of Spokane. Developments will be started on the Belcher Mountain Mining Co.'s property at Belcher Mtn. this month, the financial difficulties having been settled and capital advanced by the Winnipeg stockholders to continue the work. The Roselle Mining Co., owning 320 acres of mining claims, carrying a vein of tungsten, has been taken over by the Germania Mining Co., which has been working a portion of the vein under a misunderstanding as to titles. That latter has spent $75,000 before lawsuits compelled the relinquishment of work. The case is now before the Supreme Court of Washington, where it will be dismissed on motion of the Germania people. The amount paid for Roselle stock exceeds $50,000. William Schect, local manager for the Germania, is now at St. Paul, attending to final details. The Blue Jim Mining Co., which owns five claims on the Pend d'Orille river, has begun development of a new copper lead, which yields high-grade copper, at the surface. The New Republic Mining Co. reports 11 men employed and the intention to increase the force. The upper levels of the Republic mine, after several years of idleness, are in a bad condition and will require consid-
erable work and a great deal of new lumbering. Some prospecting is being done, and ore is being extruded in small quantities from the old stops. A rich streak was left by the old company in the floor of the No. 4 (or mill) adit-level. A winze was sunk on it, and it pinched at about 12 ft. below the collar. That streak is now being followed downward from a point on the vein about 25 ft. north of the winze, and, if it holds out, may prove a good thing.

The old company opened a level from 16 ft. down the winze, by running drifts and cross-cuts, but found nothing to justify further work. The engineers in charge recommended either a vertical shaft or that the winze should be sunk 300 or 400 ft. deeper; but the company was deeply in debt, and the mine was subsequently bought in by Ferry county for taxes. Evidently the fate of the mine must depend on what may be found below the No. 4 adit-level, although there may be considerable ore yet found above it.

—Good reports are coming from the Oversight group, in Belcher district, and also from neighboring properties. The Belcher Mining Co. has resumed work, with Bruce White in charge. A drift is being driven northward on the vein, on the No. 3 adit-level, with the intention of shipping the ore and ascertaining its practical value as a smelting product. Twelve men are employed. The Oversight M. & M. Co. has run a tunnel on the No. 3 adit-shaft, which goes down 44 ft. in solid iron sulphide ore, showing chalcopyrite from top to bottom.—Work has been resumed on the Churchill mine, on Belcher Mtn. —It is reported that the heaviest stockholders of the Winnipeg mine have bought the Rosalia interests in the Belcher Mining Co. and will soon resume work on the Belcher mine.

Republic, November 28.

OKANOGAN COUNTY.

(Special Correspondence.)—In Moses district, near the Nespelem or sub-agency, the Apache Mining Co. hopes to resume work in a few weeks on the Apache mine. It has produced some rich ore, many assays having run as high as $90,000 per ton in gold alone. Rich stringers of ore give average assays of $800 to $900 per ton in gold and silver, about 5% lead and 2 to 3% copper. The ore also contains antimony and zinc. An incline shaft was sunk 100 ft. on the vein. An adit was also driven 350 ft. to the vein, and from that point, followed an 18-in. streak of ore 15 ft. on the 100-ft. level. A winze was sunk 50 ft. on the vein below the adit-level. The majority of the ore filling is white quartz, the most of it being low grade. At the bottom of the winze the vein is seven feet wide, one foot of it assaying from $40 to $50 per ton, and a rich streak five or six inches wide follows the foot-wall. In the summer of 1891 I was at the Apache and secured specimens of ore that brought $1000 per ton, and at $800 per ton. At that time John C. Wilson had purchased the Apache claim for $1200, sunk the shaft 60 ft., and paid for the claim from the first ore he shipped.—The Multnomah Mining Co. has driven an adit from Nespelem creek, near the Columbia river, nearly 1000 ft. into Dewey Mtn., going finally through about 20 ft. of vein material and then striking into rich galena. On the hallad shaft was sunk, following a wall on which was found a little ore. By accident a shot broke through the wall and disclosed a veined of good copper ore.

—The Double Header Mining Co. has a shaft 50 ft. deep on the Double Header claim and another 80 ft. deep on the Little Chief claim. A vein has been followed from the latter and found to split; one branch, which strikes toward the Double Header adit, is being followed from the bottom of the Double Header shaft. A cross-cut shows the veenaalls to be 62 ft. apart, with mostly porphyritic conglomerate between them. On each wall is found from 18 to 20 in. of good ore, having quartz gangue and containing some ruby silver. There are also two or three stringers of ore running centrally through the conglomerate.—The San Merino Mining Co., composed of Seattle people, is operating a property, from Little Chief, and has two men driving an adit, the face being all in ore. The vein is very wide and appears much like that of the Little Chief, which it parallels.—The Rebecca M. & M. Co., one of the first to operate in Moses district, formerly found some fine ore, but closed the vein and is now cross-cutting from the bottom of a shaft, in the hope of striking it again.

Republic, November 26.

MEXICO.

JALISCO.

(Special Correspondence.)—The Molotla Mining Co., Ltd., has been organized in Toronto, Canada, with a capital of $250,000, to operate the old Molotla mines in the Hostotipaquillo district. Willet G. Miller, provincial geologist of Ontario, is the president of this company, and Frank G. Stevens, of Eztatlan, this state, is managing director. The mines were purchased by the Canadian interests from Carlos Romero, of Eztatlan, who owned them for several years, and who took out a great deal of rich ore, some carload shipments netting as high as $10,000. The Canadians are now opening new territory, and are blocking out ore supplies for a projected reduction plant, to consist of stamps, concentrators, and cyanide annexe. The Molotla mines are believed to be among the oldest in this part of Mexico, having been opened by the Indians before the Spanish occupation. It is recorded that their first Spanish owner was one Tomas Treviño, and he worked them with such success that the jealousies of other Spanish in the district were aroused. At that time a partner of Treviño was working the San Jose de Ventanas mine across the Santiago river in what is now the Jora camp of Tepic, and to communicate with him the Molotla owner arranged a system of fire signals. This signaling was delegated by his enemies to prove that he was conspireing with the devil, and formal charges to that effect were filed with the Holy Inquisition. Treviño was arrested and taken to Mexico City, and there tried, convicted, and burned at the stake. The Carizo Copper Co., of St. Louis, has recently leased its $80,000 annual custom smelter at the town of Ayutla, this state, early in December. The smelter was completed last spring and was blown in for a trial run in June, after which it was shut down pending the close of the rainy season. The company is buying outside ores, and is accumulating a big tonnage from the San Felipe, Zapatero, and Vesuvio mines near Ayutla, which were purchased last year from the Ayutla Mining Co. The production at these mines now amounts to 100 tons per day, and some of the ore runs over 12% copper and 200 gm. silver. The rich ore is sent direct to the smelter and the remainder concentrated at the mines. The company has just purchased the Zora mine in the Ayutla district, the ore of which is high in lime and low in silica, and has a good content of copper and gold. The Carrizo enterprise is of the utmost importance to this part of Jalisco, as it places smelting facilities within easy reach of the mines of Ayutla district. In anticipation of the blowing in of the smelter much development is now being done and considerable prospecting is in progress.—The Magistral-Ameica Copper Co., has been selected as the name of the concern that will operate the Magistral copper mines in the Ameica district of this State, which have just been purchased by Patrick Clark, of Spokane, and James P. Harvey, H. L. Ferey, and Fred M. Lyons, of Los Angeles, for $100,000. The four men will hold all the stock. In addition to a 100-ton plant for dry concentration, a railroad line to give the mines and mill connection with the Mexican Central railway at Ameca, ten miles distant, will be built. It is announced that the Mexican Pacific Co., of which E. L. Dohrn, of Los Angeles, is president, is now supplying the Mexican Central railway from the Ebano fields in San Luis Potosi 6300 barrels of fuel oil per day. The contract price is 55c. per barrel. The Mexican Central is steadily substituting Ebano oil for coal as locomotive fuel, and during the coming year it is expected to have all locomotives equipped to burn it. The company concerned has secured the construction of a pipe-line from the Ebano fields to the high central table-land with a view to supplying oil to industries in Mexico City and other places.

LONDON.

Institute of Metals.—First Meeting.—Electric Pumps.—Dredging in West Africa.—Mount Lyell.

The first meeting of the recently formed Institute of Metals was held at Birmingham on the 10th and 11th of November; and in every sense it was a great success. The Institute was founded during the summer and its origin is due to some extent to the requirements made obvious by the Alloys Research Committee of the Institute of Mechanical Engineers, though if it had not been for the special energies of W. H. Johnson, a great user of brass in Manchester, and Professor Carpenter, of the Manchester University, the Institute would never have taken concrete shape. The Alloys Research Committee of the Institute of Mechanical Engineers has been in existence for nearly twenty years. For a long time its functions were not fully developed, for the control was in the hands of Robertus Austen, who did most of his research work in connection with the Committee on the study of the alloys of gold, which—to be quite candid—were not of great interest to the Institute of Mechanical Engineers. To cut a long story short, the Institute of Metals has now started on what promises to be a prosperous career. Birmingham was naturally a suitable place for the first meeting, as this city is noted for its metal trades, and possesses, moreover, an up-to-date university with an excellent metallurgical department. The secretary of the Institute, Gilbert Shaw Scott, has been identified with Birmingham University, where he studied and did metallographic research work under Professor Turner. The titles and subjects of the papers read at the first meeting give a good idea of the scope of the Institute. J. T. Milton gave a paper on various physical failures of copper and copper alloys either due to bad annealing or to the presence of various impurities. Mr. Echevarri read a paper on the present position of the metalurgy of aluminum, and Mr. Philip, chemist to the Admiralty, one on phosphor bronze. Messrs. Bengough and Hudson discussed on the mechanism of annealing in the case of certain copper alloys; Dr. Desch and Mr. Rosenhain presented papers on special studies in metallography. Of course official Birmingham warmly welcomed the Institute and there were receptions, dinners, and all that sort of thing. Sir William White, late chief constructor to the Admiralty, was president and a distinguished list of vice-presidents was elected, including Richard Pearse, Norman Cookson, and Professor Gowland. The next meeting will be held in London next January.

In writing in this column about a year ago, I gave some particulars of the introduction of electric pumps in Cornwall for re-opening old mines and mentioned that in most cases there was great difficulty in making the pumps work. One of the instances I quoted was the Parihola mine, which is situated in the Gwinear district. The new owners, after trying a steam sinking-pump, put in an electric pump. Neither of these gave satisfaction. Finally it was decided that after all the Cornish pump takes a lot of beating and accordingly one has been erected. The surface plant, including 20 California stamps, is in course of erection and will be ready for work by the time ore is available. This mine is owned locally and the office of the company is at Plymouth. Another mine I mentioned a year ago was Wheal Navan, which is very near from which this old mine has been taken in hand by the Dolcoath people, and an electric pumping plant installed. Here again all sorts of difficulties arose, due to the failure of the contractors to make the machinery come up to expectations. A new electric pump of the Sulzer type was put to work in July last and unwatering has been going on since then regularly. The water-level has been lowered to about 500 ft. below adit or 670 ft. below surface. The pump is capable of working against a head of 870 ft. and will deliver 72,000 gal. per hour. As sinking goes on, the old shafts are being re-tailed and timbered. Various levels have been cleared and tributer parties are busily occupied. The question of erecting a dressing plant is in abeyance until more exploratory work has been done. The working capital originally subscribed is exhausted and there is an overdraft at the bank. The directors will shortly formulate some proposal for providing additional funds.

The Offin River Gold Estate is a company that was formed some eight years ago to acquire 50 miles of river and 100 square miles of country on the Offin river in the Gold Coast Colony, West Africa. Two dredges have been at work since 1904 and during four years have recovered bullion worth £33,365. The last 12 months produced £23,985, so that the operations are now getting into miner-like shape. The actual working expenses during the last year were £10,714 at the property and £2160 in London, together with £2190 interest on debentures, thus leaving a working profit of £734. Owing, however, to the considerable amount of expenditure in previous years, it is not possible to prepare a profit-and-loss account for the year. The capital issued is 200,000 shares of £1 each as purchase price, 52,917 shares for cash, and £30,000 of debentures. During the last few months 50,000 additional shares carrying preferential rights have been issued for cash with the object of sending out two new dredges. One of these is at work already and the other will follow before long. A good deal of money has also been spent recently in blasting a channel through the numerous dikes that cross the river, so that now the dredges can be floated to any part between Dunkwa and the Pra river. The dredges used are not the heavy ones to which you are accustomed in the West of America, but are of light steel frame work suitable for work in tropical countries and in shallow rivers running through jungles. I hope to be able soon to send you illustrated information about these dredges.

The cables summary of operations at Mount Lyell during the six months ended September 30 shows that a larger profit has been made than during the previous six months, details of which I gave in your issue of June 13. The total production was 4460 tons of blister copper containing 4394 tons of copper, 336,654 oz. silver, and 9425 oz. gold. The total amount of ore treated was 199,969 tons, averaging 2.62% copper, 1.69 oz. silver, and 0.9 dwt. gold. In the previous half-year the copper content was only 2.46%, and the output of blister copper 4301 tons, a fact which accounts partly for the increased profit. At the beginning of the six months about 9000 tons of copper unsold. This has been disposed of, and there were 852 tons of the current half-year unsold on September 30. The average price for the copper sold during the half-year was £60 9s. The total
proves were £152,157, as compared with £292,950 during the previous half-year. Dividends at the rate of 1s. 9d. per share, absorbing £65,000, are being paid out of this and the accumulated surplus, to the benediction of the North Montevideo Cross-cuts compared spur the that this obtain R. 1908, fissure the close south, proceeding to the has new MINING one good be being the the ft. the the opened among tions, mine development the is of the of & development, the is from Conejos, and have been opened further supplies and the reserves have been increased by 163,675 tons, even after deducting 65,446 tons taken out during the half-year. The reserves at the North mine are now 719,333 tons, running 5% 5% copper, 1.23 oz. silver, and one grain of gold. The outlook for the Mount Lyell Mining & Railway Co. is therefore excellent.

MEXICO.

Monterey Steel Works Resuming.—Durango Iron & Steel Co. —San Miguel del Mezquital Mines.—Conejos Sulphur Deposit.—Penasco Mining Co.—Oil Developments in Chihuahua.

The rumored resumption of work by the Monterey Iron & Steel Co. seems about to be realized. A force of men has been busy for some time over the necessary preparations, a large stock of between 50,000 and 30,000 tons of both coke and iron-ore has been received, and it is expected that early in December will see the plant in full operation, which will mean a weekly pay-roll of about £20,000. This has been made possible by a number of large orders, chief among which is one from the Mexican National railroad for 85 lb. rails, to replace the 70 lb. rails now in use. It is the intention of the Company to place heavier rails over the entire line between Mexico City and Laredo. The order given the Monterey steel plant is for 75,000 tons of steel rails to be delivered over a period of two years, 20,000 to be delivered in 8 months. Should the steel plant remain in operation that length of time it will be the longest run that has been made there and will prove of great benefit to Monterey.

It has also been recently stated that the Durango Iron & Steel Co., which has been idle for a number of years, has finally interested New American capital, and that all the old debts will be paid off and work resumed. This company owns a large portion of the famous iron mountain, known as the Cerro del Mercado, just outside of the City of Durango, at the base of which mountain the plant is situated. This immense deposit of hematite is one of the largest, if not the largest, known in the world, and is an ideal ore for the iron-blast furnace. Durango will await anxiously the realization of this report. Another hoped for influx of foreign capital of interest to Durango is from Los Angeles, California. It is said that H. Winninghoff has been able to interest men of means in his San Miguel del Mezquital mines, situated in the valley at the edge of the town of that name 8 miles south of Catalina station, which is an hour's ride on the Mexican International railroad east of Durango. These mines have been idle four years or more, and current capital is estimated to be in the neighborhood of two millions, with an expected output of two thousand tons of ore per day. The prospecting will stop with the aim of work to be carried on without loss of a day's work.

The El Porvenir Co. is doing important work near Parral, under the direction of Nat. P. Wilson of Denver; other interested parties are M. E. Peters, G. W. Huddleston, and Juan F. Brauns. The oil-stands were said to bear a close resemblance to those of Pennsylvania. Messrs. Hearst and Keene are supposed to be quietly acquiring ground in the vicinity. Mr. Troxel was also associated in that work, but seems to have broken away to handle the present enterprise; which has been examined by John S. Duffey of Pittsburg, reported satisfactory, and work ordered to proceed as soon as the drilling machinery can be placed on the ground.

PARRAL, MEXICO.

The El Porvenir Co. is doing important work near Parral, under the direction of Nat. P. Wilson of Denver; other interested parties are M. E. Peters, G. W. Huddleston, and Juan F. Brauns. The oil-stands were said to bear a close resemblance to those of Pennsylvania. Messrs. Hearst and Keene are supposed to be quietly acquiring ground in the vicinity. Mr. Troxel was also associated in that work, but seems to have broken away to handle the present enterprise; which has been examined by John S. Duffey of Pittsburg, reported satisfactory, and work ordered to proceed as soon as the drilling machinery can be placed on the ground.
MINING AND SCIENTIFIC PRESS
December 5, 1908.

ROSSLAND, BRITISH COLUMBIA.
Granby Consolidated.—Profitable Operation.—Boundary Output.—Dominion Copper.—Centre Star Group.

At a meeting of the board of directors of the Granby Consolidated M. S. & R. Co., held in New York on November 10, a 2 1/2% dividend was declared, payable December 15. For some time the local stockholders in this concern, and others who are directly or indirectly interested in the company's affairs, have been expecting action of this kind, and while rumors of a convincing character have been circulated throughout the district during the past two weeks, there was nothing certain until the official statement of the board of directors was published. This is the tenth dividend that the Granby company has declared since December, 1903, and will bring the total profits paid to December 15 next up to $3,506,620. The payment of this last dividend and that of June, 1908, being both on a 2% basis, representing a disbursement of $276,000, have a most significant bearing on the low-grade copper-gold mining industry of the Boundary district. They go to prove that the mining of the low-grade copper deposits that exist in the hills about Phoenix can be done at a fair profit, even with copper at an abnormally low market-price, and will effectually dispel the few doubts entertained when the Granby mines resumed on the first of the year. The average extraction per ton from Granby ore is 25.42 lb. copper, 0.2865 oz. silver, and 0.0454 oz. gold. For the year ended June 30, 1908, the average price received for copper was 13 1/2c., from which figures it will be seen that a large tonnage must be mined and great economy exercised in mining and smelting the ore, in order that a profit may be realized for the stockholders. Up to and including the week ending November 21, 1908, the Granby company has mined at Phoenix, and sent to the smelter at Grand Forks, 950,425 tons of ore. It is officially stated that by means of the diamond-drill there has been developed and blocked out a greater tonnage than has been mined during the year; in other words, the reserves at this date are over 950,425 tons. The Granby company has fairly riddled the hill with diamond-drill prospect holes, and it is stated that the cores so far taken out, if joined, would measure over six miles in length.

The enlarged furnace at the Grand Forks smelter is operating satisfactorily, and it is now thought that this experiment will be a success, and that the other seven furnaces will be enlarged, one at a time.

With shipments from the Boundary district of 36,674 tons of ore for the week ending November 21, 1908, the total tonnage sent out from this district during the past nine years passes the 7,000,000-ton mark. Of this exception, tonnage for a young industry, the Granby has contributed about 10 per cent. As each year passes, the record of ore shipments has shown that the copper mining industry of the Boundary has assumed more important proportions and has more firmly established itself, and at this writing the future looks bright. Steady shipments are now being made from the B. C. Copper Co., Mother Lode, and Oro Denoro mines, as well as the Granby mines, while the Con. Mining & Smelting Co. of Canada is making regular shipments from the Snowshoe and is conducting developments on both that property and the Phoenix amalgamated group.

The liquidator of the Dominion Copper Co. has succeeded in raising a sum of money, and the men still employed about the mines, caring for the pumps, etc., were paid their wages last week, but the final arrangements for funds to meet the unpaid August and September payrolls have not been made. The work of establishing the concern on a reorganized basis is proceeding slowly but steadily. In the

parallel in the Roca Mole group, belonging to J. H. Robeson, A. H. Reidel, and Nat. P. Wilson. It has one strong vein, with several cross-veins, the former being a fissure in the diorite. The old workings comprise a 255-ft. shaft and 600 ft. of lateral work. The ore is silicious, carrying silver and gold, with only a little lead. It is proposed to begin operations here in January.

The PROVIDENCIA mining Co., of Worcester, Mass., has a 70-acre group one mile east of the Pallimilla. It has a series of veins striking northeast. The principal of these has been opened by an incline shaft 256 ft. deep and a vertical shaft 300 ft. Some driving has been done on the vein from the 300-ft. station, showing 3 to 5 ft. of ore carrying silver and lead, the lead occurring as galena and carbonate. At one of the shafts is a crusher, a set of rolls, and some hand-jigs, by which concentrate is being made and shipped. J. D. DAVIS, in charge, is in Denver, is in charge.

The Pallimilla, which delivers its ore from the mine to the railroad at Parral over a 2 1/2-mile aerial tramway, is ship-

ping some of its best ore but the principal effort is now being made to drive a 1500-ft. cross-cut from the base of the hill to tap the working shaft 600 ft. below the collar. This cross-cut will be used mainly for drainage.

The Prieta, situated on the outskirts of Parral, belonging to the Parral Con. Mines Co., and managed by D. H. Bradley, has been shipping a car of ore per day up to a month ago, but shipments have been suspended for the present on account of the low price of silver, although development work is in progress. These ores are base and complex, carrying iron, lead, zinc, and silver. The silver occurs in the main as argentite, though there is a small part as a chloride. In the lower levels is some copper. This property has a complete plant, comprising an electric hoist, air-compressor, and ore-testing mill. El Tajo, a well developed mine adjoins Prieta, but it belongs to the American Zinc Extrac-

The Hidalgo M. Co., managed by James I. Long, U. S. Consul at Parral, has 17 partly developed mines in the district, some of which have been good producers. Mr. Long is preparing to make some cyanide tests, and this is one of the indications that cyanide plants will become a factor in this district. James I. Long is at the head of the Parral & Durango Railroad Co., which operates a road from Parral westerly a distance of 75 kilometres. Chas. F. Gehrhardt and brother have taken a 10-year lease and bond on the La Buena and El Vuelca mines, 30 miles from Rosario, in Durango, on which they are beginning work. The properties are sufficiently developed to show a sulphide of iron and lead, carrying gold and silver. It is said to be high-grade.

State of Chihuahua, Mexico.
Supreme Court at Vancouver the National Trust Co. of Toronto has asked for judgment of $890,000 on the mortgage they hold, given two years ago. The application was opposed. Henry P. Keefe, consulting engineer for the B. C. Copper Co., examined the principal mines of the Dominion Copper Co. a week ago. No information has been divulged, and sentiment is divided as to whether the examination was made on behalf of large shareholders in the company, or whether the B. C. Copper Co. will endeavor to lease the mines, treating the product in their up-to-date plant at Greenwood.

The Centre Star group, Le Rol, and Le Rol No. 2, Ltd., in Rossland camp, are producing steadily. Nothing has interfered with their regular production during the year, and they have made a fair profit on their operation. The Le Rol has paid off a large part of the company's debt, and there is a good body of ore in sight on the 1650-ft. level; the work in other parts of the mine is giving good results. A rich strike has been made with the diamond-drill in the Le Rol No. 2, Ltd., but the shoot will have to be driven on before anything definite will be known. Assays of the core show the vein contains $75 to $300 in gold, silver, and copper.

**BUTTE, MONTANA.**

November Output. — _Anaconda Fire._ — New Find of Copper near Ashcroft. — Interesting Details. — New Smelter.

In November the mines of the Butte district produced 28,262,400 lb. copper, against 28,864,410 in October and 29,655,000 in September. For the last 10 days of November the production of the Anaconda company was slightly curtailed on account of the fire in the Anaconda and Never-sweet mines. Notwithstanding denials, there is reason to believe that the fire in the Anaconda mine is more serious than it has been at any time previously. The various companies contributed to the October total as follows:

A new copper district, from which the reports are so good that they seem almost incredible, is being developed near Ashcroft, B. C., by a number of Butte men. It is in an entirely new country, a virgin field, the property being situated 350 miles east of Vancouver and 12 miles from the Canadian Pacific railroad. It consists of three claims, a total of 156 acres, located along the vein. In British Columbia it is 1650 ft. square and is without extra-lateral rights. The ground was located about three months ago by G. H. Chattaway, who was prospecting, when W. W. McDowell of Butte heard of the find and visited the district, with the result that he took a three years' option at a big price. John Kerrigan, a practical miner, was sent from Butte to make an expert examination, and his report states that the Butte men have found one of the biggest copper propositions in the country. The vein is 6 ft. to 28 ft. wide on the surface, has been traced a distance of 2900 ft., and the samples taken from surface cuts and from an adit that is being driven on the vein at a depth of about 100 ft. give an average assay of 13% copper, the run of 14 samples being from 4 to 25%. The vein occupies a fissure in granite. About $7000 worth of ore was taken out in driving the tunnel, and the dump assays 15% copper. A point about 77 ft. ahead of the present face of the adit shows a width of 28 ft. of ore on the surface. There is talk of concentrating this ore, which would be abundant with so rich a smelting ore. If the development work proves satisfactory, it is the intention of the owners to build works on the banks of a lake about a mile distant. There are two large rivers within 10 miles of the mine, offering exceptional possibilities for power, and the country for hundreds of miles is covered with timber. Twenty-eight miles from the mine are the Nicolay coal mines, which furnish a fine grade of coking coal. The Canadian government has already signed its willingness to build a wagon-road to the mine, and the plans of the owners include the building of an electric road from the Canadian Pacific, a distance of 12 miles, and to the Nicolay coal mines. Many fine samples of bornite have been sent to Butte. No company has been organized; the parties interested are W. W. McDowell, W. E. Reynolds, C. J. Kelly, H. B. Byrne, Phil Gillis, Walter Lewis, Guy W. Stapleton, Geoffrey Lauzier, L. A. Hellbromer, all of Butte. J. W. Martin, formerly foreman of the Raven mine, is in charge of the development operations.

E. P. Mathewson, the amalgamated Co.'s smelter expert, with a number of men, has gone to Utah to do the work preliminary to the building of the new smelter for John D. Ryan and associates, who obtained a contract from the Utah Consolidated to treat the latter's output for a period of 10 years. The first work to be done is to build a branch railroad from Tooele, on the Salt Lake road, to the site of the new smelter. As soon as the road is completed material will be hauled to the ground and work on the smelter begun. The new smelter will be capable of treating 6000 tons of ore daily, with a capacity to treat 2000 tons of ore daily. The contract with the Utah Consolidated provides that the smelter shall receive of that company's ore up to 1200 tons per day. Its present output is 300 tons per day.

The Butte Coalition is opening one of the biggest ore deposits in the Butte district. This big deposit is being developed in the Minnie Healy mine, on the 1400 and 1500-ft. levels. Only one stop has been opened so far, but the big vein is being put in shape for a heavy production in a month or six weeks. At present the vein is mined through the Tramway shaft, but in another week the ore will be hoisted through the new Tramway shaft, with which all the new levels have been connected. The ore taken out at present from that vein assays 6% copper as an average. All the new levels are connected by adits. The lower working of the Minnie Healy are below the fire, the fire in the property being confined to a portion of the mine above the 1190-ft. level where mining has been entirely abandoned. The fire is burning away from the Minnie Healy, and is worst in the Boston & Montana properties, adjoining the Minnie Healy. When the work planned on the lower levels of the Minnie Healy is completed a connection will be made with the old shaft from the 1900. The fire-drifts will be built headed and, securely sealed.
which will permit the company to mine the ore in that part of the mine. The Traunus shaft will become the main working shaft for the Coalition Co., and the old Minnie Healy surface plant is being dismantled. Nearly all the buildings have already disappeared, and the head-frame has been lowered and taken apart. The old shaft has caved a great deal, and will be useful only as a chimney for the smoke and gas forming in the mine from below. The West Boston & Narragansett is doing very well, and the old Minnie Healy has given the WestNarragansett more trouble with the fire in that part of the district than the Butte Coalition Co., but is following the example of the latter: is bulkheading the upper levels and confining the fire, while a practically new mine is being opened at greater depth and under the fire zone. It is claimed that the fire originated in the old stopes of the Minnie Healy, which were filled with all sorts of waste, including hot ashes. By the time the Minnie Healy was one of the properties of F. Augustus Heinze and the United Copper Co. It appears that when a fire once starts in a copper mine it is impossible to extinguish it, and the only thing that can be done is to keep it confined and under control.

KALGOORLIE, WESTERN AUSTRALIA.

September Output.—New Type Orebody.—Methods of Ore-treatment.—Dust Prevention.

The usual progress reports for September from the principal mines indicate much work of a sound nature in the deeper workings. At 1900 ft. in the Boulder Main Reef shaft, the No. 208 level is cut at 1550 ft. in the Kalgoorlie gold ore good ore was cut, being 11 ft. in width; and at 2300 ft. in the Great Boulder fair ore is being worked, although not so rich as on the 2200-ft level. During the month West Australian mines produced gold valued at $2,950,000, the Kalgoorlie district returning $1,600,000, and a grand total of $31,600,000. The September yields of the principal mines were as under:

The Sons of Gawalla South announces ore reserves of 25,150 tons worth $11 per ton; and the Ivanhoe at the end of June had 914,770 tons assaying $12.24 per ton. Arrangements have been completed whereby the Oroya-Brownhill Co. takes over the Brownhill Extended property. The former is now working the Brownhill, Brownhill Extended, the Oroya North and South Blocks, the Central and West Boulder, and Kalgoorlie Mint leases, all on the eastern side of the ‘Golden Mile,’ and connected with the Brownhill mill by an aerial tram and a light tramway for trucks drawn by horses. Until lately the Company kept its mill going on ore mainly from the Brownhill-Iron Duke lode. This is a peculiar ore-body, unlike anything else on this field, and may be described as a pipe-like shoot of lenticular character, for which purposes for assay were sent west about 30°, while the general course of the pipe is nearly due south, with a pitch in that direction of about 1 in 3. It outcropped in the Brownhill lease, entered the Ex-

tended at about 350 ft., cutting through one corner of that ground, entered the Associated Northern at 330 ft., leaving the southern boundary at 500 ft., entering the Oroya North block and traversing this, entering the Associated lease at about 1000 ft., where it gradually loses its shape and assay values. Although the orebody was worked for this great length, it had several breaks in each lease; still, it has been a wonderful gold, and the dredge is operating a south-chiefly calaverite and petzite, and free gold were extracted. In the Brownhill kalgoorlite or coloradoite was found in fair amounts. From the Brownhill lease to the Associated the ore now being mined from the shoot is only of medium grade. It is reckoned that the Oroya had the richest ore near its boundary with the Associated Northern, but the following smelting results will give an idea of some of the big hipped from the latter mine before its mill was erected:

Oxidized ore treated at local mills...3795 tons for $130,000
Smelted at Dupo, N. W., in 1900...1077...160,000
Smelted at Dupo, N. W., in 1902...7046...590,000
Smelted specimens...14...92,000

The total gold won from the lease in its whole length to date is approximately $27,000,000, and dividends amounting to $13,400,000 have been paid. Of these totals the Oroya-Brownhill has treated about 750,000 tons, obtaining gold valued at $21,000,000, and has paid dividends of $10,300,000; the Associated Northern treated 230,000 tons, yielding $6,000,000, and has paid $3,100,000 in dividends. Exact figures of production from the lode have been difficult to procure.

A short description of the treatment of the ore from this lode may be of interest, as two very different processes are in operation. The ore is of a schistose character, containing 60% silica, calcite, telluride, and pyrite, making a total sulphur-content of about 5 per cent.

The Oroya-Brownhill Co. crushes its ore in a fast-running battery of 50 heavy stamps, using no copper plates. The mill pulp is classified before going to the Wilfey tables, is re-ground in pans before going over more tables, and the whole pulp from the tables is ground to slime in tube-mills, settled, the thick slime run from the settlers into covered vats, agitated with KC and bromo-cyanide, and filter-pressed, the residue being carried away by a belt conveyor to a dump containing perhaps 750,000 tons. The concentrate from the Wilfeyes is roasted in Merton furnaces, ground in pans, settled, agitated with cyanide, and finally filter-pressed.

On the other hand, at the Associated Northern, the ore is broken in a Gates crushe, crushed through a 25-mesh wire-screening in No. 5 Krupp mills, roasted in Merton furnaces, ground to slime and amalgamated in pans, settled, run into vats, agitated with 0.05% KC, filtered-pressed, and disposed of by belt-conveyor. The extraction in both mills is from 90 to 94%, and the cost runs to $2.75 per ton at the Brownhill and $2.70 at the Associated Northern. Both plants have their little treatment-troubles, but on the whole the work is satisfactory. In years past there has often been a poor extraction, and after sampling the dumps at the two mines, it was found that the bulk would pay for re-treatment. The Brownhill is now erecting a Cassel plant of 15,000 tons monthly capacity; while the Associated Northern has been re-treating for some time upward of 2700 tons per month by mixing, agitation, and filter-pressing at a cost of 60c. per ton. This is interesting, as at the Lake View Consols they were taking 5000 tons monthly by a talc-fueled process has a cost of 62c., the extraction in both cases being about equal.

This is a windy month here, and the dumps have been blowing about in a disagreeable manner, making the Golden Mile unhealthy to work and live on, besides which the dust does much damage to the machinery, and the oil consumption rises. Several of the mines are arranging to spray their dumps with salt water from the shafts. Where used during the month at the big mines totalled 26,072,900 gal., ranging from 4,894,000 gal. on the Great Boulder to 624,000 on the Associated Northern.
SALT LAKE, UTAH.

Contract for Utah Consolidated Smelter.—Tooele Valley Railroad.—Changes in Management.—Pioche Mines Sold.—Railroad to Yerington.

The contract awarded by the Utah Consolidated Mining Co. to W. D. Thornton of Butte, Montana, whereby the latter agrees to provide smelting facilities for the treatment of ores from the Utah Consolidated mine in Bingham for a period of ten years, together with the announcement that the construction of a new smelter on the site selected for it by the Utah Consolidated in Tooele county, would begin at an early date, has been received with a display of profound satisfaction by Utah mining men. While the new smelter is intended expressly for the convenience of the Utah Consolidated, at the same time conditions have shaped themselves in such a way that when Mr. Thornton’s company is organized it will enter the field as a vigorous competitor of the American Smelting & Refining Co., which at the present time has things nearly its own way in Utah, in so far as the treatment of copper ore is concerned.

The Guggenheims, or the American Smelting & Refining Co., who are minority stockholders in the Utah Consolidated, apparently have made a failure of their tactics in trying to block the erection of a competitive smelter in Utah. They even went so far as to threaten injunction proceedings; but President Broughton has found a way to avoid this, and shareholders of the Utah Consolidated have the option of subscribing for $500,000 worth of stock in the new smelting company, which will probably be done, if they have not already done so. A conveyance of all the land involved for use as a smelter site, together with water rights, smoke easements, and the like, has been made to Mr. Thornton, and when his company is formed it is said several persons prominently identified with the Amalgamated Copper Co. are to figure in the enterprise.

The construction of the new smelter is to be under the direction of E. P. Mathewson of Anaconda, who is to be chief engineer. It is expected that ground will be broken within the next month, and that the concrete work will be started before the end of the year; while the surveys for the standard-gauge railroad, to be known as the Tooele Valley Railway, have been completed, and in all probability the contract for the grading will be let within a week. This line will connect the smelter with the main lines of the Western Pacific and the San Pedro, Los Angeles & Salt Lake railroads at Black Rock, a distance of about 25 miles. One of the first things that should be considered is the building of an electric trolley line from Tooele City to the smelter, about four miles away, which will be utilized principally in conveying employees to and from their work.

It now costs the Utah Consolidated Co. 40 cents per ton to get its ore hauled over the Rio Grande tracks from Bingham to the smelter at Garfield, aside from the expense of maintaining an aerial tramway 12,000 ft. in length. This freightage will be done away with entirely, for in the future ore will be conveyed direct to the smelter from the mine by an aerial tramway system only a little more extensive than the present one. It is claimed by President Broughton that the contract with the new smelting company will save the Utah Consolidated 67.5 cents per ton in the cost of treatment at the smelter; hence it does not take much figuring to show that the company will save $1 per ton, or approximately $300,000 per annum, on the basis of handling 800 tons of ore daily.

A change in the management of the Newhouse Mines & Smelters Corporation will occur on December 1, when Lafayette Hanchett will retire, to be succeeded by T. J. Drummond, the present superintendent. Mr. Hanchett, however, will continue to be general manager of all other enterprises of which Samuel Newhouse is at the head. Several changes will be made in the directorate of the Newhouse Mines & Smelters, and also in the Boston Consolidated, early next month.

Several mining deals involving property at Pioche, Nevada, were consummated at Salt Lake City last week, the purchasers being John A. Kirby, John T. Hodson, and W. H. Webber, all of whom are large shareholders, and the latter manager, of the Nevada Hills mine, at Fairview, Nevada. The properties secured were the holdings of the Pioche Consolidated, Abe Lincoln, and Miller groups, the latter being situated adjacent to the Prince Consolidated, in which enormously rich silver-lead ore has been recently found.

The Mine Owners’ Association of Utah has entered a protest against the movement to take off the tariff on lead, and has delegated Clarence E. Allen, mines manager of the United States Smelting, Refining & Mining Co., and C. E. Loose, manager of the Sioux Consolidated Mining Co., to represent the interests of Utah mine and smelter owners before the Ways and Means Committee of the House of Representatives at Washington.

The building of a railroad into the Yerington, Nevada, district appears to be an assured fact. William H. Bancroft, vice president and general manager of the Oregon Short Line, under whose jurisdiction the building of this piece of road will come, has gone on record as saying that the matter has been settled, in so far as the advisability of entering the camp is concerned. There are certain things to be done yet by the mining companies, but these are only matters of detail. Engineers of the Harriman system some weeks ago reported that the camp has the tonnage necessary to justify the expense of a new road; that the Nevada Douglas alone would warrant the investment, regardless of what has been accomplished in other properties, which are regarded as being nowise unimportant.

The quarterly report of the Utah Copper Co., covering the operations of that company during the months of July, August, and September, has been released, and shows the net earnings during the period to have been $496,656, while the income from other sources amounted to $473,5, making the total receipts $501,291. The gross production of copper was 12,006,252 lbs., an increase of nearly 40%, as compared to the previous quarter, the average cost of which was 8.73c. per lb. Stripping operations continued throughout the quarter, at the rate of approximately 87,000 yd. of capping per month, which was equivalent to the stripping of 0.8 of an acre per month. During the quarter the underground ore sent to the mills amounted to 32%, and the steam-shovel ore 68% of the total.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Gold melts at 2192°F, and silver at 1832.

Crocoite is associated with gold in the quartz of the Ninchi Tagils, in the Urals.

Volcanic vents on the surface of the earth at the present time number about three hundred and fifty.

‘Poppet heads’ is the English and Australian equivalent for the Western ‘gallows frame’; for all of these the term head-frame should be used.

Trachyte is from the Greek word meaning rough. The rock usually has an uneven fracture, due to the angular sandine and the porosity of the ground-mass.

Krennerite is a telluride of gold, approximating calaverite as regards composition, but differing from the latter in possessing a perfect cleavage. It is named after J. A. Krenner, of Budapest.

Conversion of centimetres to inches, and vice versa, may be readily accomplished by use of the ratio: Inches : centimetres = 160 : 63.

One inch = 2.5399541 cm., and — — = 2.53968.

The Severn tunnel, which carries the Great Western railway, of England, under the estuary of the Severn river, is not quite 4½ miles long. It penetrates strata of conglomerate, limestone, carboniferous beds, marl, gravel, and sand, at a minimum depth of 44 ft. below the deepest portion of the estuary bed.

Phyllite is a name applied to thinly laminated slaty rocks containing mica, usually of the kind known as seifcite. They may have resulted from extreme metamorphism of aluminous sedimentary rocks, but excessive shearing under great pressure will also convert many crystalline rocks, such as felsites, into phyllite. In the process of metamorphism the feldspars are altered into mica.

The horse-power of falling water may be estimated by the following formula, which assumes an efficiency of 80% for the wheel:

$$ hp = \frac{hq}{11} $$

in which $h$ is the effective head, in feet, and $q$ is quantity of water, in cubic feet, per second.

Accretions in blast-furnace smelting of copper ores are greatly augmented by irregular distribution of the charge in feeding. In fact, accretions are often directly produced by such irregularity. A furnace cannot be properly fed by pouring the charge down a chute, nor can distribution be effected by dropping the feed from a hopper. A device that will pour the mixed charge from a car as wide as the furnace-mouth itself, discharging the burden uniformly as it traverses the furnace top, will overcome the formation of accretions to a large extent, and will sometimes prevent them altogether.

Cyanide of sodium appears to be as energetic a solvent for gold as the potassium salt. Differences in efficiency have often been reported, but the result of prolonged practical experience all over the world indicates that either salt may be used without causing decrease in extraction. Cyanide solutions are inert toward the compounds of the less common metals which are usually found in ores.

Portland, as a name for cement, was first used by Joseph Aspelin, who, in 1824, took out an English patent for a product made by the calcination of a mixture of limestone and clay. It was so called because of the fancied (and in reality very slight) resemblance between the cement and the famous oolitic limestone quarried for building purposes at Portland, England, and known to all English architects and engineers as ‘Portland stone’.

Oxidation of the metallic content of minerals during crushing has long been recognized. Sulphides are oxidized to sulphates, and it was pointed out by Manzelius, of the Swedish Geological Survey, that the ferrons iron in minerals is oxidized to the ferrie form under the same conditions. Recent tests to confirm or disprove this have shown an increase during fine grinding of ores of as much as 22% in the relative amount of ferrie iron present.

Mica varies widely and spasmodically in price, owing partly to the erratic character of the deposits. The mica market is liable to sudden gorging and to equally sudden depletion. To a large extent it is now under control of the General Electric Co., which has been said to own mines capable of supplying all its needs. In 1907 the average prices realized at points of delivery on the Atlantic Coast were $14 per ton on scrap mica and 33c. per lb. on sheet. The price of sheet mica varies according to size, ranging from 25c. per lb. for material cutting 1 by 3 in., to $1.50 when as large as 5 by 8. Freedom from blisters, checks, and stains is imperative for mica to be marketed in sheet form.

Lime-burning today is not generally done by feeding alternate layers of limestone and wood. Exterior fire-boxes, in which the fuel is burned, are placed a few feet above the discharge-hopper of the kiln. The ‘mixed-feed’ type of kiln, however, is cheaper to construct, and is somewhat more economical of fuel. The product, on the other hand, is less uniformly burned, is apt to be discolored, and it contains the ashes and clinker of the fuel. A kiln 6 ft. diam. at the top and 7 ft. at the bottom, 25 ft. high, will have an output of about 7 tons of quicklime per 24 hr. The burned lime produced per cord of wood will vary widely with the kind and dryness of the fuel. Perhaps three tons of lime to one cord of pine wood may be taken as a realizable output.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

National Bureau of Mines.

The Editor:

Sir—I wish to call the attention of your readers to certain phases of the proposed legislation establishing a National Bureau of Mines. It will be recalled that an act establishing such a bureau in the Department of the Interior passed the House of Representatives last May, was favorably reported by the Senate Committee on Mines and Mining, and is now on the Senate calendar. As finally worked out, the bill provides for a strictly technical bureau charged with the study of problems related to mining with a view to fostering, promoting, and developing the mining industries of the United States. It is to have no police powers, no duties of inspection, and no special responsibility regarding the mineral lands of the public domain. It is designed to do for the processes of mining and metallurgy what the Geological Survey is doing for mining geology and ore deposits; being co-ordinate with the older organization and taking up the work where the latter leaves off.

It is believed that the Senate will promptly pass this bill and the Bureau will be established. The act carries no appropriation, though, as amended, the technologic branch of the Geological Survey, with the existing appropriations for investigation of fuels and of structural materials, is transferred to the new Bureau. The extension of the work is wholly in the hands of Congress, and is to be determined from year to year by appropriations.

It is a curious and interesting fact that, whereas the demand for a bureau or 'Department of Mines' arose first in the West, and the main credit for its achievement, if the present move be successful, must go to the American Mining Congress, the miners of the Eastern and Middle States seem likely to first get the benefits. The only work now provided for is that on structural materials and on fuels heretofore carried on by the Survey. While these are of national importance, the main interest in them is not in the West, but the East. Benefits to the West must come from the study of its own mining and metallurgical problems. That there are such problems, and that careful scientific study of them will be of great assistance, is not doubted by anyone familiar with the field. In the MINING AND SCIENTIFIC PRESS of August 20, W. A. Callicott lists a considerable number of problems relating to so well established a process as cyanidation that demand even now scientific investigation if that process is to be improved, and its application extended. In the number of August 29 Bertram Hunt says: 'Little progress has been made in the development of the technical application of the cyanide process compared to the mechanical improvement. Most cyanide chemists and managers have little leisure and few appliances for research work.' This truly reflects the present conditions, and yet our practising engineers must have a basis upon which to build. The need of fundamental research probably has been felt by every engineer who has faced a difficult problem in ore treatment.

In mechanical concentration the condition is perhaps even worse. In the judgment of some of our most thoughtful and most successful metallurgical engineers, mechanical concentration is now as perfect as it can be made with our present knowledge. The mechanical engineer has caught up with the chemist and physicist, and is demanding more data on which to build; and yet our treatment is far from satisfactory. It is common to over-estimate the saving made in concentrating mills because the latter are hardly ever equipped with adequate sampling devices. At Butte, Montana, where sampling is complete and accurate, it is stated that approximately 90% of the ore goes to the mills, and that of this 76% is saved. There is some additional saving from 'slums' sent to the blast-furnace, but this is not always feasible. At Garfield, Utah, where the sampling, while not so complete, is still unusually carefully done, the mill-saving is approximately 70%.

In Clear Creek, Colorado, the writer can state, on the basis of a number of runs—with sampling of headings checked against smelter receipts, instead of the usual tailing assays—that the ordinary saving is between 50 and 60%, and occasionally it runs down to 30%. Rarely, and under only most favorable conditions, does it go up to 90%. In the lead and zinc districts of the Mississippi Valley there are no accurate means of determining the saving made, but the best authorities put it, in moderately good practice, at about 70%. It is probably safe to say that of all the sulphides milled in the United States there is an annual loss of 25 to 33%. The value of this in dollars and cents, in even individual properties, is enormous. The manager of one of our copper companies, the largest, estimates that the copper in his tailing, at present prices, has a value of approximately $5000 per day.

No one is so foolish as to think that all this can be saved, and yet no one should doubt that careful studies will point the way to a saving of some of it. It should further be remembered that each per cent of added saving not only affords a profit, but makes possible the opening and working of additional mines. The West has a very direct interest in any movement to improve these and similar conditions, and I suggest a full and frank discussion of Western needs, followed by a united effort to obtain from Congress such help in meeting them as the conditions of the public purse will allow. If the Mining Bureau is established, it certainly should be instructed to take up certain of the specific problems of the Western States and should be provided with the means for doing so. Doubtless the officers of the American Mining Congress will take the lead in this, as in the previous efforts for legislation. They will need support, but first of all they will need advice from the technical men of the West as to what problems are most pressing.

For the purpose of starting such a discussion, I
venture to suggest the following problems as proper for such a Bureau to take up:

1. Systematic investigations of underground methods of work, carried on from camp to camp, with a view to the formulation of the exact conditions under which each method is applicable.

2. Similar investigations of the methods of haulage, hoisting, drainage, ventilation, and other mechanical engineering problems related to mining, and the publication of appropriate reports.

3. A study of the fundamental chemistry of the cyanide and other leaching processes.

4. A study of the physics of the magnetic, electrostatic, and various flotation processes, with a view to the discovery of underlying principles and of constants necessary to their wider application.

5. A study of the methods of oxidation, with a view to developing, if possible, a leaching process for refractory ores without roasting. In the Black Hills the saving on the 'blue ores,' when treated without roasting, amounts to 35%. Because of its high cost, roasting preliminary to cyanide treatment is locally out of the question.

6. Experiment on wet concentration, directed especially toward the settling and recovery of slime.

7. Investigation of the character, strength, deterioration, and evenness of grade of the powders used in the metal mines, together with the analysis of the gases resulting from their use. This might be supplemented by the formulation of simple directions regarding storage, handling, and use of these powders, discussions of powder-gas poisoning and the proper methods of resuscitation, and similar topics. Leaflets should be printed and placed in the hands of as many miners as possible, with a view to saving life and preventing accidents. The rapid expansion of the industry brings in annually so many untrained men that a campaign of education of this sort is much needed. It is to be remembered that in this country we have no schools for miners—only for mining engineers—and that at the same time there is in mining no regular system of apprenticing.

8. Investigation, in co-operation with the Forest Service, of the problem of timber supply and timber preservation in the mines. In some Western mines the timber bill amounts to half the cost of mining.

9. Study of the effect of mining on the pollution of the streams, with a view to presenting the fair claims of the mining industry in anti-débris and anti-pollution agitation.

It would probably be unwise to take up all these investigations at once, as it would be difficult or impossible to find suitable men for undertaking them, but the list will indicate something of the range of problems to be met. To handle this work properly a carefully chosen corps of men must be brought together, and there will be many difficult problems of organization. It would be foreign, however, to the spirit of the West, to submit to difficulties without trial, and for myself, I am convinced that united and long-continued effort will accomplish much along each of the lines indicated.

II. Foster Bain.
be less resistance to overcome than when using straight ribbed steel, or any other kind of steel commonly used.

Chlorination in California.

The Editor:

Sir—In replying to Mr. W. J. Adams' comments on my article published in the Mining and Scientific Press of October 31, I will say that I spent several months last summer in visiting and inspecting some of the large metallurgical plants in Colorado, and made a special study of the various types of mechanical furnaces in use for desulfurizing ores; but did not see any that completely filled all of the requirements for a chloridizing furnace. I believe, however, that a combination of some of the types could be formed that would ensure uniformly good results, and avoid the fusing action so common in both the hand-reverberatories and the mechanical furnaces now in use.

The conditions governing a good chloridizing roast are as follows: the dried and pulverized ore should be ignited as soon as possible after being charged, to hasten the operation and to give the furnace a maximum roasting capacity. After the ore has been thoroughly ignited it should be rabbled frequently to ensure uniform burning, and a sufficient quantity of air should be allowed to pass over the burning ore to not only supply oxygen for the reactions and to remove the spent gases, but also to carry off a part of the excess heat and allow the ore to roast slowly without generating sufficient heat to produce sintering. After the first atom of sulphur has been removed and the sulphates commence to break up, the ore loses heat rapidly and should be advanced toward the firebox, and a sufficient quantity of external heat supplied to maintain the ore at a cherry red color until the greater part of the sulphates have been decomposed and the combined base metals oxidized.

A little salt will now assist in decomposing some of the more refractory sulphates, by forming volatile chlorides of the base metals and allowing the remaining atom of sulphur to either unite with the sodium or to pass off as sulphuric anhydride. But if the temperature should be too high, some of the gold will also be chloridized and will commence to escape as a volatile chloride. For this reason I believe that the salt should be added after the heated ore has been discharged from the furnace, and I would advise the use of a rotating cylinder having the receiving end brick-lined and the discharge end water-jacketed, so that the chloridized ore would be discharged in a cooled condition for subsequent treatment. As there would probably be some volatilization of gold even under the most favorable conditions, I would advise exhausting the fume from this chloridizing cylinder and forcing them through a scrubbing tower, to absorb and recover any gold that might be volatilized. If, however, one of the Crosby furnaces that Mr. Adams describes can be depended upon to roast ore so as to yield 99% recovery of the gold, there is little more to be desired. I have obtained an extraction of 98.5% on a small sample of ore roasted in the assay-muffle, when roasting without salt, but in actual practice, working on a large scale, I have never been able to bring a month's run up to over 96% bar-recovery of the purchase price of the ore, and I have so often obtained much less than that percentage that I felt like 'patting myself on the back' whenever I was able to make so good an extraction.

Wilton E. Darrow.

State Mining Bureau.

The Editor:

Sir—I have had called to my attention an editorial which was published in your journal under date of November 21, 1908, and which is headed 'State Mining Bureau'. This editorial relates to an article on gold dredging, published in the Pacific Miner, and regarding same, I wish to say I did not supply the article, nor did I claim the credit for it. Upon learning that the article had appeared in the Pacific Miner, on November 13 I wrote to the editor of that journal asking that a correction be made in the next issue, which will probably be done.

Regarding the articles which are appearing from time to time in the Mining and Scientific Press, I wish to say that if you would take the pains to correctly inform yourself of facts before going off half-cocked in your attacks not only on the State Mining Bureau, but upon myself, I believe it would redound more to the credit of the journal which you represent. The statements made not only do a great injustice to the State Mining Bureau, but are deliberate attempts, resulting from personal animus, to discredit work which has the support of every legitimate miner in this State. I use the word 'legitimate' advisedly. I do not refer to the political miners nor sharks who attach themselves to the mining industry, and who have been defended by you in many instances.

If you had one spark of fairness in your composition, you would honestly investigate before adopting the mud-slinging tactics you have pursued. You have printed a mass of lies, and I have proven to you that you lied. An honest journalist, when confronted with facts showing he had made misstatements, would endeavor to correct such mistakes, but not so with you.

However, when the reasons, political and otherwise, are considered, which inspire these attacks, and of which reasons I am well aware, it is needless to expect that the Mining and Scientific Press, under your administration, would adopt the system of fairness for which it was once noted.

San Francisco, November 21.

L. E. Aubury.

[Mr. Aubury's letter arrived last week, after this department of the paper had gone to press. His letter speaks for itself. It answers nothing, but it saddles the responsibility for the dredging article on the editor of the Miner. This we anticipated, as will be seen by referring to the criticism appearing in our]
issue of November 21. Fortunately, the readers of this journal need no statement from us that we try to be fair and truthful, nor the assurance that we have no concern with politics, save as it affects citizenship in a broad way. Mr. Aubury has not proved, nor can he prove, that our criticism of the Bureau and of his management, are not justified. Upon the only occasion when we held a conversation with him, he made a number of statements that we ascertained afterward to be grossly false. At that time we were misled by an appearance of candor. The Trustees know that the statements made in this paper are true and prompted by a proper spirit. It is time for them to take action.—[Editor.]

**Alternating Exhaust and Pressure Ventilation.**

The Editor:

Sir—A note in your last issue, referring to a practice in certain Victorian mines, suggests the following method of controlling the outflow of gases in coal mines, always troublesome, often disastrous.

With a well designed system of ventilation the air current can be easily and quickly reversed. I would suggest that while men are in the mine the fan be run to force air in, and at all other times in the opposite direction. To intensify the "exhausting" effect the intake might be throttled. Of course, the change in pressure thus produced could have little, if any, effect on gases held in the solid coal, but it seems to me it would greatly reduce the amount retained in crevices in the coal and in open places in the mine, and thus relieve the situation during the danger period.

This plan is, of course, inapplicable to mines that never rest, but, from the difficulty people in Nevada experience in getting coal, I am disposed to think there are at least some that do not work the whole twenty-four hours.

W. F. Collins.

**Deep Lead Mining in Australia.**

The Editor:

Sir—In a very interesting article on this subject appearing in your issue of October 24, the author, Mr. D. H. Browne, stated in conclusion that "deep lead mining had been somewhat under a cloud for several years, but this is due principally to the great cost entailed in pumping out the heavy flow of water, and not because the gold contents of the lead is inferior."

In the case of the recently deceased Loddon Valley Co. the low grade of the gravel encountered, together with its spotted character, are given as the causes of its failure. It is true that the heavy running expenses due to pumping cost in this mine increased the total working cost, but it cannot be denied that the nature and the value of the gold contents of the gravel found were most disappointing. Messrs. Biewick, Moreing & Co., the general managers, in their final report, made the following statement: "The general results have been on the whole disappointing and discouraging. The wash has unfortunately proved to be spotty and the gold contents very unevenly distributed. Indeed, so evident has been this tendency that it has been found unsafe to place too great reliance on prospects obtained from even the cutting-up drives. Later paneling of areas thus tested has given results much lower than the average called for by the trials. While it is true that the territory tested by the underground workings represents but a fraction of the total area of your holdings, yet the spotted nature of the wash, together with the fact that no encouraging ground has been opened up during last year's work, make it in our opinion, unadvisable to expend any further money on the property."

Mr. C. Algernon Moreing, in his speech to the shareholders of this company, further emphasizes this point of low values and spotted character, and "personally did not feel inclined to go any further, or advise anybody else to go any further."

**Information Wanted.**

The Editor:

Sir—I am anxious to obtain some information about hand and power-drills, either of the churn or rotary type, for boring holes of 3 in. diam. and over for blasting purposes only—say, in quarry work. Are they largely used anywhere? If so, where? Will they do the work economically and save 'springing' holes? If so, at what rate of speed per hour of boring, and at what cost per foot or metre of hole in different classes of rock. Will they do efficient work to a depth of 60 ft., or in the ease of hand-machine to, say, 25 ft.? I am flooded with catalogues and makers' letters, but should like some notes and records of practical experience by disinterested users. Statements of charges used in blasting such holes would be of great practical interest too.

[We hope one or more of our readers will contribute information based upon their own experience.—[Editor.]]

**Crosby Furnace.**

The Editor:

Sir—In today's Mining and Scientific Press I notice an article by W. J. Adams, in which he describes a furnace called the Crosby. To some of us older ones it comes like an echo from the long ago. The Crosby furnace came down from 1868, when the Crosby-Thompson process created a good deal of sensation in Colorado, where all kinds of processes were in vogue. The furnace was the only good thing in it, and it did really good work. Mr. Adams gave me the first information I have had that it was ever used outside of Boulder county, Colorado, where a great many processes were born and died. It was developed by the late Lawrence Thompson, of Boulder, and to my own knowledge did excellent work. I have often wondered why it never came into use, as it is cheap and efficient. The patent on it long ago expired.

San Francisco, November 21.
**RESEARCHES IN DIAMOND MAKING.**

Written for the MINING AND SCIENTIFIC PRESS
BY F. H. MASON.

The art of alchemy was started with the avowed intention of discovering the philosopher's stone and the elixir of life, and with these rewards in view as a fillip to the early philosophers, they persevered in their researches, and ultimately founded the science of modern chemistry. While neither the philosopher's stone nor the elixir of life has been discovered, the science of chemistry has yielded rewards to its devotees, and today offers a large field for profitable research.

There is one branch of chemistry in which apparatus necessary for research is costly and easily frangible, and for which ample financial resources are essential. It is doubtful if even the more fortunate members of the profession would devote themselves to this branch were it not for the fact that there is a fillip behind it, as there was behind the old art of alchemy. I refer to the study of chemistry under very high temperatures and enormous pressures. Behind this research is the possibility of finding a process for the manufacture of precious stones, in an endeavor to imitate nature's laboratory. I do not wish to infer that the study of the behavior of substances at high temperatures and under excessive pressures is being carried on wholly with this view. What I desire to state is that there is the chance of making a valuable discovery, and that adds zest to the work, as the hope of the philosopher's stone inspired the alchemists of old.

The study of chemistry at high temperatures and under excessive pressures is likely to throw light on many subjects now in darkness. The most recent work on this subject has been done by Richard Threlfall, and he has employed some original apparatus, which appears to be less costly and more efficient than that which has been previously used. Former experimenters have generally employed gases or liquids to communicate the pressure to the substance to be operated upon. Mr. Threlfall conveys his pressure by means of a steel plunger working upon crystalline graphite. Crystalline graphite flows readily at medium pressures, and makes a practically frictionless fluid. The apparatus is simple, and although I referred to it as frangible, it can only be so considered relatively to the excessive temperatures and pressures it has to withstand. It consists of three main parts: (1) Apparatus for producing pressure. (2) A vessel capable of withstanding pressure. (3) Apparatus for electric heating. The pressure is applied by an ordinary hydraulic jack capable of lifting 50 tons, and provided with an accurate and sensitive gauge. The electric heating is provided by a 10 to 20-kw. transformer, wound on both sides with several separate windings, which can be connected so as to suit the requirements of the different experiments. The pressure-vessel (Fig. 1 and 2) consists of two cylinders of steel, AA, BB. Each cylinder is turned and ground to exactly the same external diameter, and the faces which are intended to be in contact are ground so as to fit with almost optical precision. Each cylinder is bored as shown, and after the cylinders are clamped by the carefully turned clamps CC, the whole is ground to a perfectly cylindrical form. The clamp is insulated from the cylinders by a thin sheet of special packing, and in boring the clamp, allowance is made for this. The two metal cylinders are separated by a sheet of mica about 0.5 mm. thick. The sharp edges of the hole are chamfered. The cylinders are held together by means of the cross-pieces DD, EE, and the bolts FF, made of mild steel. The plug H is of hardened tool-steel, and when screwed up the head fits snugly in the recess in E, so that the pressure when applied is not borne by the threads.

The upper cylinder is provided with a plug of hardened tool-steel, J, with the end accurately ground to fit the recess. The ram K is made of hardened tool-steel, and fits at the top against a piece of hardened tool-steel let into the insulated bar G. This insures the application of the pressure to the ram in the direction of its length. The pressure-vessel is insulated from the upper clamping bar by means of a sheet of mica between A and D. The electric current to produce the heat enters the apparatus by the
bar K and leaves by a connection to the plate E. As the two cylinders are insulated from each other and from the clamp C, the full potential of the current is thrown on the mica plates between A and B, and, if suitable arrangements are made, must pass through the substance under experiment in the pressure-vessel. Purified magnesia has been found to be the best substance with which to line the pressure-vessel. Magnesia is not easily compressed. It was found in this apparatus that a pressure of 50 tons per square inch only compressed the magnesia about 3 mm. below the ram. Therefore in lining the pressure-vessel only 2 to 3 mm. could be compressed at one time, and the cylinder had to be filled gradually.

When the hole in the cylinders is filled with magnesia, the cylinders are placed in a lathe and a hole bored through the magnesia, 3 to 4 mm. diam., and deeply chamfered at both ends. The magnesia tube is then rammed full of graphite, and the graphite continued half way up the plug J, to form a reservoir to draw upon as required. Finally the ram is inserted and the graphite pressed with more than the full pressure it is intended to use. A current of 500 to 600 amperes is then passed through the graphite. Almost immediately the pressure-gauge begins to fall, owing to the melting of the magnesia, for, however hard it be packed, it will be found to make room for graphite when it melts. The current is kept on for five or six seconds, the pump being worked vigorously all the time to keep up the pressure. The apparatus is allowed to cool, the ram is taken out, and the graphite scraped out. The tube of fused magnesia is then ready to receive any mixture it may be desired to experiment upon. Should the mixture be a non-conductor, a wire or rod must be inserted as a heater. Mr. Threlfall appears to have confined his attention principally to the study of carbon. Small electric-light carbons were subjected to pressures of from 50 to 117 tons per square inch, and to temperatures calculated to be in the neighborhood of 8000° C. The rods were converted entirely into graphite; as viewed under the microscope, the original granular appearance was completely lost.

Graphite in its natural state, artificial graphite, and Ceylon graphite purified by fusion with caustic potash, washing, and then digesting, first in hydrofluoric and hydrochloric, and afterward in hydrofluoric and sulphuric acids, and thoroughly washing, were all experimented upon at temperatures between 7000 and 8000° C., at pressures varying from 50 to 100 tons per square inch. The most thorough search was made at the end of each experiment, but in no instance was the smallest specimen of diamond found. The graphite in some experiments was converted into large brilliant crystals; sometimes it showed increased density, and sometimes diminished density. The pressure was always maintained while the apparatus was cooling, in order that the crystallization should take place under pressure.

One experiment was made with a mixture of silicon carbide and iron filings, with the expectation that the silicon would leave the carbon and join the iron,

$$\text{SiC} + \text{Fe} \rightarrow \text{FeSi} + \text{C},$$

and that the nascent carbon might crystallize in the form of diamond; but the iron appeared to have melted and been forced into the magnesia tube before the temperature of the reaction was reached.

While Mr. Threlfall's experiments have up to date been negative, so far as concerns the making of diamonds, the results are of considerable interest. The weak part in the apparatus appears to be that a high temperature cannot be maintained for any length of time: the longest recorded experiment was one in which the current was maintained for ten seconds. In this case the magnesia lining was completely melted and the carbon concentrated in the centre. If it were possible to materially increase the thickness of the magnesia lining, the substance under examination might be kept at a high temperature for a considerable period. The ideal conditions, as Mr. Threlfall points out, would appear to be the heating of carbon to a high temperature for a short period with some substance in which it is soluble, and then to maintain it at a temperature at which the carbon would begin to separate for a long period, and to keep it under high pressure during the whole time. In this way it might be hoped to build up crystals of large size, and should the carbon crystallize in the form of diamond, the product might be of some commercial value, and not a mere chemical curiosity.

Iron and silver have been usually employed as solvents for carbon in attempts to make diamonds. Henri Moissan in his successful attempts used iron. While of course iron is present in the matrix in which diamonds are found in Nature, it is practically demonstrable that they have not crystallized in metallic iron, and that the latter has then been oxidized away. It is possible that carbon may be soluble in substances at high temperatures, and under excessive pressures in which it is not soluble at lower temperatures and without pressure. This seems a hopeful line for research.

Condensation of smelter fume by a process of refrigeration has been proposed by Franklin R. Carpenter. This would necessitate cooling the fume to about -10° C., at which point the SO₂ would be liquefied. The heat of the furnace gases would be used to do the work of refrigeration, after the manner of ice-machines of the absorption type. As an over-production of sulphuric acid at places where the demand was inadequate would result from this process in the case of most smelting plants, Mr. Carpenter proposes further to utilize a reducing atmosphere by which the SO₂ would be reduced to solid sulphur, which could be separated by passing the fume through bags, as is now done at many smelters to save the solids carried from the furnaces with the gases.

A portable eating station is in service on the Wyoming lines of the Chicago & Northwestern railroad. A change in schedule made the station at Douglas no longer convenient, and so a restaurant, composed of four cars, was substituted, that could be moved from place to place as occasion might require. The four cars comprise a dining room, kitchen, lunch room, and bunk car for the crew.
THE OREBODES OF THE BUNKER HILL & SULLIVAN MINE.

*All of the ore of the Bunker Hill & Sullivan, Last Chance, and Sierra Nevada mines lies in fine-grained sericitic quartzites thought to belong to the Revett formation. The orebodies are definitely related to a persistent fissure which strikes N. 45° W. and dips to the southwest at an average angle of 38°. Both dip and strike, however, show local variation. This fracture, locally known as the "foot-wall fissure," is in this report called the Bunker Hill fissure. It has been traced almost continuously from the Sullivan claim, on the east side of Milo creek, to a point about 290 ft. down the west slope of the ridge between Wardner and Deadwood gulch. Southeast

and northwest of these respective limits, the Bunker Hill fissure is not definitely known. By some it is thought to be identical with the Sierra Nevada lode; by others to pass through the Senator Stewart, Silver King, and Crown Point claims.

The fissure has all the characteristics of a considerable fault; but the two walls are lithologically identical, and whatever faulting has taken place has not perceptibly affected the structural relations of the rocks at the surface. The amount of the displacement along the Bunker Hill fissure, and its character, whether normal or reverse, are unknown. By reference to the geological map, it may be seen that the Bunker Hill fissure lies on the south side of the 65°. The beds are in many places sharply flexed and are traversed by numerous fissures which are usually filled with a gouge of crushed quartzite. At a distance estimated at 1500 ft. from the portal the tunnel cuts a band of dark slate, possibly 50 ft. wide, such as is characteristic of the lower part of the Burke where it grades naturally into the Priehard formation. The presence of this slate suggests that in spite of irregularities of dip the quartzite near the mouth of the tunnel belongs near the base of the Burke formation and rests in a generally normal position upon the Priehard.

Near the first bend in the tunnel, or about 4000 ft. from the portal, the quartzite is so badly broken for
a distance of several hundred feet that the tunnel required lagging. The Osburn fault probably coincides with this disturbed ground. South of it the beds have a more nearly east-west strike, ranging from N. 50° W. to west, and a general southerly dip of 50° to 80°. These seem to be the prevalent directions of strike and dip of the beds throughout the mines. Near the orebodies, however, the bedding planes are in many places obscured by sheeting or shattering of the quartzite. Ripple marks serve to distinguish bedding from sheeting, but these are not invariably present. The boundary between the Burke and Revett formations was not recognized in this tunnel.

So far as ore deposition is concerned, the Revett quartzite found in the Bunker Hill & Sullivan and Last Chance mines may be regarded as homogeneous material. The formation of the orebodies appears to have been conditioned by fissuring and the disposition of the ores exhibits no observable relation to bedding planes, nor is there anything to suggest that, within the general zone of mineralization, particular beds have been more favorable than others to the accumulation of ore. Details of folding may thus be eliminated from economic consideration.

The only eruptive rock known in the Bunker Hill & Sullivan and Last Chance mines is a much altered greenstone dike which is exposed at the half-way switch in the Kellogg tunnel. The dike is about 50 ft. wide and may have been a diabase or diorite. It is now full of secondary quartz, chlorite, carbonates, serpentine, green amphibole, and other alteration products. The dike is far in the foot-wall country and apparently has no connection with the orebodies, which are found only in the quartzite of the hanging wall. A similar dike is exposed in the Black Hawk tunnel.

The Bunker Hill fissure is well defined throughout the productive parts of the Bunker Hill & Sullivan and Last Chance mines, and is usually recognized with ease by its characteristic appearance. There is almost invariably a thin seam (1 or 2 in.) of tough, nearly black clay gouge, which usually shows two or more planes of movement and slickensiding. According to Mr. Easton, this gouge contains kaolinite and manganic. Under this seam is a white, creamy, or buff band, ranging from a few inches to a foot or more in thickness, of crushed quartzite which in places is so finely powdered as to form what is usually termed sugar quartz. This white band contrasts strikingly with the black clay seam, and this is very characteristic of the Bunker Hill fissure. The sugar quartz usually passes gradually into the less disturbed foot-wall quartzite. On the hanging-wall side the black seam is in some places in contact with ore, in others with shattered but barren quartzite.

Although the quartzite of the foot-wall has been well explored, all the ore so far found in the Bunker Hill & Sullivan, Last Chance, and Sierra Nevada mines has lain in the hanging wall of the Bunker Hill fissure. That no ore should have been deposited beneath the persistent seam of dark gouge characteristic of this fissure is remarkable, as the quartzites of the foot-wall are identical in character with those of the hanging wall, and are in places extensively fissured and broken, though usually less so than in the hanging wall. In the hanging wall, in addition to much irregular fracturing, two sets of fissures may be distinguished, one approximately parallel to the Bunker Hill fissure and the other nearly at right angles to it.

The zone of fissured quartzite in which the orebodies occur has a maximum width of 300 ft., measured perpendicularly to the Bunker Hill fissure. Within this zone, either in contact with the foot-wall or separated from it by barren quartzite, are numerous irregular orebodies, usually without definite walls or boundaries. Locally, however, the ore may be bounded on one side by the clay gouge of the Bunker Hill fissures or on one or more sides by some of the subsidiary hanging-wall fissures. It is difficult to convey a satisfactory idea of the dimensions of orebodies so lacking in regularity. Individual payshoots may be 500 ft. in length, 100 ft. or more in width, and 300 or 400 ft. in depth. The whole fissured zone, 300 ft. in width, may, in a broad sense, be regarded as a single great lode, within which the partly overlapping and partly connected orebodies are not uniformly distributed in the plane of the zone but are grouped into at least four fairly distinct shoots. The most southeasterly of these is the Sullivan ore-shoot, which has been extensively stoped above the Reed level, but which is as yet unexplored below the sixth level of the Bunker Hill & Sullivan mine, although it will probably soon be reached on the ninth level. On the west side of Milo creek, extending from the Richmond tunnel up the hillside to the open-cut just above the Bunker Hill No. 1 tunnel, is the original Bunker Hill ore-shoot, which above the Reed level might perhaps be regarded as two shoots. This is apparently the same great ore-shoot which is now being stoped on the eighth and ninth levels, and in the new tenth and eleventh levels, below the Kellogg tunnel.

Still higher up the slope a third shoot, which may conveniently be designated the Blacksmith ore-shoot, from the name of the first stope, comes to the surface and has been extensively worked down to the sixth level. Below that level very little ore belonging to this shoot has as yet been found.

All three of the foregoing shoots, so far as developed, pitch to the northwest at an angle of approximately 45°. A fourth shoot is cut in the Tyler tunnel, near the crest of the ridge separating Milo creek from Deadwood gulch, and seems near the surface to have a northwest pitch, like the others. This shoot, however, which is the one whence the Last Chance mine has obtained the bulk of its ore, lies in the pitching trough formed by the Bunker Hill fissure and the Jersey or Skookum fissure, and the local northwest pitch observable in the Tyler workings is replaced at greater depth by the southwest pitch due to the dip of the Jersey fissure. The general relation of the Tyler, Jersey, or Skookum ore-shoot to the Bunker Hill and Jersey fissures is shown diagrammatically in Fig. 1.

The Jersey fissure, or, more correctly, fissure zone, has an approximately northeast-southwest course,
and thus meets the Bunker Hill fissure nearly at right angles on any given level. It dips to the southeast, apparently at an average angle of 35°; but as it is less regular and has been less continuously explored than the Bunker Hill fissure, the average dip has not been accurately determined. The principal fissure of the Jersey zone resembles in general character the Bunker Hill fissure, and is related in a similar manner to orebodies of irregular shape and distribution lying within its hanging wall. Very little ore in the Last Chance mine has been found along the Bunker Hill fissure except where it is joined by the Jersey fissure zone, which, so far as known, ends at the junction. Under the Jersey fissure zone, and lying approximately parallel to it, is a second fissure zone, known as the Sanbo. This is narrower than the Jersey zone and has not been nearly so productive. The relation of the Sierra Nevada vein to the Bunker Hill fissure is a moot question, and is likely to remain so until some exploration is made of the neglected block of ground lying between the Last Chance stopes and the Inez shaft.

The orebodies of the Bunker Hill & Sullivan mine are usually of entirely irregular form, and the longest diameter of the body may lie at any angle with the Bunker Hill fissure. The absence of definite limiting walls to the ore is a characteristic, although not invariably, feature of these large bodies. Masses of nearly solid galena grade outwardly into ore containing larger proportions of gangue, and finally into barren country rock. Here and there, however, the ore ends abruptly at a fissure whose walls show evidence of some movement since a part at least of the galena was deposited. Such a fissure, for example, forms a local hanging wall to part of the large March orebody on the Kellogg level. Similar fissures in some places traverse the orebodies, and the ore forming their walls is usually slickensided. Nowhere, however, are the fissures important faults. Some orebodies rest directly upon the foot-wall of the Bunker Hill fissure and are slickensiding, showing that movement along this fissure has continued since the ore was deposited.

The orebodies of the Last Chance mine, though in many places fully as irregular as in the Bunker Hill & Sullivan, lie chiefly along the Jersey fissure-zone, and many of them are roughly tabular parallel to that zone. The Senator Stewart orebody, as opened in 1904, was about 300 ft. long. It strikes N. 35° E. and dips at a steep angle to the southeast. The ore forms an irregular, elongated, ill-defined mass in much fissured quartzite. It apparently follows a zone of cross-fissuring and may be related to the Bunker Hill fissure much as is the Jersey ore-shoot. The position of the Bunker Hill fissure, however, is as yet undetermined west of the Last Chance mine. The main orebody apparently does not reach the surface, being cut off a short distance above the main tunnel by some gouge-filled fissures with low angles of dip.

In the Silver King mine a few small bunches of ore have been found in the badly shattered quartzite forming the hanging wall of the Osburn fault. The ore is said not to occur at a less distance than 20 or 30 ft. from the slate foot-wall. In the Crown Point mine the ore, which has been mostly stope out, formed an irregular rolling sheet in the shattered hanging-wall quartzite. In some places it was nearly horizontal, but in general it had a dip of 20° to 30° northeast. It thus dipped toward the southward-dipping Osburn fault, orebody and fault coming together near the main tunnel level in a line of junction which in some parts of the workings is 25 ft. above and in others a few feet below that level. No orebodies of importance have ever been found below this junction. The ore is said to have ended abruptly at the slate foot-wall, and to have shown some slickensiding, probably due to comparatively recent movement along a fault whose major dislocation antedated the period of ore deposition.

The mineralogical character of the Bunker Hill & Sullivan ore is simple, galena and siderite constituting over 90% of the whole. Associated with these minerals are usually small quantities of quartz, sphalerite, and pyrite. Some tetrahedrite and chalcopyrite are reported from the Sullivan stopes and from the Tyler workings. These minerals, however, are not characteristic of the principal orebodies of the Bunker Hill & Sullivan mine—such, for example, as the March stope on the ninth level. The best ore from such stopes consists of rather fine-grained masses of galena with subordinate siderite. This grades into ore in which the siderite exceeds the galena, and this into barren siderite. The ore is principally a replacement of the Revett quartzite, but the replacement is closely connected with fissuring and some of the galena was deposited in open spaces. A typical mass of ore of moderate richness shows a base of matrix of pale brown siderite traversed by countless reticulating veins of galena. In the poorer ore these veins are fairly distinct and show only slight metasomatic enlargement of the original cracks. But in the richer ore they coalesce into bunches of solid galena. It is plain that the quartzite was first fissured and replaced by siderite. Subsequently the siderite was shattered and solutions deposited galena in the intersecting fissures and, by metasomatic replacement, in the siderite of their walls. Where the little fissures were particularly numerous and the other conditions for deposition favorable, the siderite has been wholly replaced by galena. But the process was not entirely so simple. Some of the galena is traversed by stringers of siderite and by veins of galena of different (usually finer-grained) crystallization from the mass of the ore. Moreover, here and there galena directly replaces the quartzite. It is evident, therefore, that there has been some recurrence of conditions favorable to the deposition of galena and siderite, and probably also of quartz, pyrite, sphalerite, and other metasomatic minerals. In the Bunker Hill stopes quartz and pyrite are usually most conspicuous in the transition zone from ore to country rock.

The ore of the Skookum or Jersey fissure zone, which has afforded the bulk of the output from the Last Chance mine, has certain mineralogical features which usually serve to distinguish it from the typical Bunker Hill ore.
COPPER DEPOSITS OF WHITE HORSE.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. Rickard.

The town of White Horse, on the Yukon river and in the Yukon Territory, is the terminus of the White Pass & Yukon railroad, which is a part of the established route to Dawson. White Horse is 110 miles north of Skagway and 460 miles south of Dawson. At a distance of two or three miles from White Horse there is a belt of copper-bearing country that extends for about 10 miles in a nearly north and south direction. The whole tract has been covered with locations, the activity in this regard being disproportionate to the actual work accomplished in the way of mining. A little real prospecting has been done on four different groups of claims, all of which are readily accessible over the roads constructed by the Government of the Yukon Territory.

Four miles from White Horse, a straggling frontier town, is a large group of claims that was bonded last year by Col. W. S. Thomas, of Guffey & Thomas, Pittsburg. About $80,000 is said to have been spent in preliminary work, and then the ground was abandoned, save for the Copper King claim. A shaft on the neighboring Anaconda claim is 20 ft. deep, with an open-cut. In approaching this prospect the road passes under a bluff of white limestone, suggesting the character of the country rock. In the shaft it is seen that the ore consists of an impregnation of copper in the limestone, the best showing being for a width of 5 to 10 ft. and a length of 100 ft. Bornite is associated with tremolite, garnet, and quartz. There is an intrusion of granite near-by, but the lode is not a contact, although it is obviously the result of contact metamorphism such as has been studied and described so lucidly in Kemp's papers.*

The Pittsburg Colonel is said to have spoiled the market for mining property near White Horse by taking options at absurdly high prices; thus, a claim 1,500 ft. square with a 3 to 5% copper lode across it was bonded for $250,000. Such a load would break the back of any boom. The cost of mining in this locality is high, owing to heavy freight charges and expensive labor. I shall speak of this later. Let us proceed to other mines.

The next group of claims is called the War Eagle. Here we (Scott Turner and the writer) saw a nicely arranged dump, with pretty fragments of variegated bornite fringing the foot of the pile of ore that had come from shallow workings. The erubescite was accompanied by chalcopyrite, white tremolite, brown garnet, and calcite, in a silicified limestone. In the wash covering a portion of the surface I saw fragments of hornblende-granite, which occurs close-by. Garnetiferous limestone constitutes the ore-channel. The ore is not compact, but scattered, so as to yield a low-grade product. There is a width of 20 ft. through which the copper mineral is scattered. A shallow adit 100 ft. long connects with a winze 50 ft. deep. In this there is a nice showing of chalcopyrite. The ground is hard, and it breaks short because of the tremolite.

The Copper King was the next mine visited. T. H. Kerruish is superintendent, and by his courtesy we went through the 243 ft. of adit that attains a depth of 80 ft. below the surface. A winze 63 ft. deep exhibits a lode 5 to 8 ft. wide in garnetiferous limestone. The granite is not 100 ft. from the orebody. On the adjoining claim—the Carlisle—the ore is within 8 ft. of the granite. Some 19% copper ore has been shipped from the Copper King, and some 22% stuff from the Carlisle. This was smelted at the Tyee Copper Co.'s smelter, at Ladysmith, on Vancouver island. Such selected ore contains a couple of ounces of silver and from $1 to $5 in gold. A 5-drill Ingersoll compressor, with one 2½-in. drill in use, and a steam hoist capable of work to 500 ft., constitute the equipment. The men are paid $3.25 and board (worth $1.25 per day). When engaged in shaft-sinking, $4 is paid. Work was started this year on May 15. The drift from the adit struck breciated limestone and oxidized ore, suggesting a cavernous formation. The ore at this place also contains bornite with tremolite and garnet.

In riding from one mine to the other, the traveler will see numerous and different kinds of stakes and bench-marks left by the topographical, geological, and geodetic surveys of the Territorial and the Dominion governments, but he will see but few signs of the use of a transit underground. It seems as if

*Some New Points in the Geology of Copper Ores. MINING AND SCIENTIFIC PRESS. March 30, 1897. Also The Copper Deposits of San Jose, Tamaulipas, Mexico. Trans. A. I. M. E. Vol. XXXI, pp. 178-202.
some of the itinerant surveyors might give the prospectors a line once in a while.

On leaving the Copper King, the road, along Macintyre creek, is seen to cut through the granite. The garnetite limestone follows the contact with the granite, but the ore itself is away from the granite, although enclosed within the garnetite limestone. Approaching the Pueblo workings, the road cuts through drift material well suited to road-making. The Pueblo was owned by the British America Co., one of Whitaker Wright's flotations, until 1906. It is now controlled by Byron White, of Spokane. C. P. Seale is in charge. A large mass of copper-bearing hematite in limestone is exposed in open workings. The dimensions are 215 ft. one way and 325 ft. the other, with a face 33 ft. above the level surface. A shaft and winze prove the continuity of the orebody to a further depth of 92 ft. A cross-cut 125 ft. long shows about 100 ft. of ore, with the breast in stuff of the same character, but poorer. The entire mass is cut lengthwise by a crevice 2 to 3½ ft. wide, having a slight dip to the east, filled with glacial drift. This open fissure goes down at least 25 ft. The walls are eroded, as if by water. The granite is 150 ft. east of the ore. When at its best the ore exhibits chalcopyrite and even cuprite. The average is 3% copper and 40% iron. About 700 tons has been shipped at various times to the Tyee and Crofton smelters, chiefly the former. This orebody has been sampled so frequently that it is in danger of removal by too inquisitive engineers. The faces of ore show the channeling of many samplings and testify to visits from experienced men.

Another important mine is the Arctic Chief, which I did not see. But R. F. Jones, the superintendent, is an old Colorado acquaintance, from whom I obtained reliable notes. Moreover, this mine and the White Horse copper district in general have been described by W. J. Elmendorf in a series of four articles appearing last February in The Mining World. On the Arctic Chief there are two adits, one of which is intended to cut the ore 170 ft. in, and at a depth of 110 ft. The ore is bornite and chalcopyrite with magnetite, associated with garnet and epidote. It is said to average 4½% copper, with $1 in gold and 2 oz. silver per ton, for a width of 40 ft. and a length of 200 ft. By way of comparison with the hematite ore of the Pueblo, it can be said that the latter carries about 2 oz. silver but only a trace of gold. Gold is rarely to be seen in the White Horse copper ores, although most of the selected stuff assays about $1 in gold. The principal orebodies carry an excess of iron and command a low rate for smelting.

The cost of transport to the railroad has handicapped the development of this district, but an exaggerated notion of the value of the mines has been a greater drawback. The drop in the market price of copper proved a stunning blow. This summer there were only 25 men at work in the whole copper district, but a branch line of railway was being constructed for a distance of 11 miles from the main line so as to tap the principal workings. This work was stopped before it was finished, but it is hoped that it will not be abandoned. We hope also that the mine owners will do their share to test the value of the copper deposits. Not enough has been done to warrant either the statements of promoters or the condemnation of a critic. These limestone contacts are ideally adapted for prospecting with the diamond-drill. The operators seem to hug the idea of defined lodes; they shut their eyes to facts that prove unmistakably that the deposits are irregular impregnations close to a contact between limestone and granite.

TIN DEPOSITS OF SEWARD PENINSULA.

Stream tin was discovered in the York region of Seward Peninsula during the fall of 1900 as a heavy and objectionable constituent which accumulated in the sluice-boxes of the placer-gold prospectors, afterward identified as cassiterite. This true nature of the mineral once known, search was directed toward finding a wider distribution of the tin-bearing gravels and toward discovering the bedrock source of the cassiterite, the search being stimulated by the failure of the gold placers of the region and the high market price of metallic tin in recent years. In a report by Adolph Knopf, recently issued as Bulletin No. 358 of the U. S. Geological Survey, the following observations are made:

Developments in this region have been sufficient to demonstrate, at least, that the granite-limestone contacts are not favorable places to hunt for commercial bodies of cassiterite ore. Quartz porphyry dikes, locally known as lodes, or even as quartz veins, have been prospected to some extent, owing to the fact that the original discovery of lode tin in Alaska was made in a mineralized or altered dike of this character. The value of any such dike depends on the number of cassiterite stringers which it contains, and the closeness with which they are spaced. Of itself a quartz porphyry dike has no value. The unwelcome fact should be speedily realized that few of these dikes hold out any inducements whatever as prospective tin producers. Most of the developments throughout the region are still in the prospecting stage, and many of the open-cuts have not uncovered solid bedrock. No tin-bearing rock, except at one place on Lost river, has yet been blocked out. Small holes in the ground, which give no clue to either dip, strike, or persistence of the orebody, are held at enormous figures. The great need of the country is less desultory prospecting. The slate area deserves more careful examination, as it is possible that valuable quartz veins may exist within its confines. The distribution of stream tin in Aniokivik river and its tributaries proves that the stanniferous mineralization is not limited to the region at the head of Buck creek, but is more widely spread throughout the slate belt. It is probable that a great granite mass, of which the stocks at Brooks mountain, Tin creek, and Cape mountain are protruding bosses, underlies the entire York region. As the region becomes better known and more thoroughly prospected, additional discoveries will probably be made from time to time.
SAN ANTONIO DE POTO HYDRAULIC MINE, PERU.

Written for the Mining and Scientific Press
By W. E. Gordon Firebrace.

This famous placer mine is situated in the District of Poto, Province of Auca, Department of Pano, in southern Peru, at an altitude of 15,000 ft. above the level of the sea. The mines were discovered in the year 1553, shortly after the conquest of Peru by the Spaniards, and from the many old workings, reservoirs, canals, and ditches which are found, as well as the enormous quantities of tailing to be seen, it is evident that ground-sluicing had been carried on upon an extensive scale. It was not until the year 1893 that any attempt was made to work the mine in a systematic manner, when an American mining engineer named Meyers was engaged by Juan Manuel Peña y Costas, the owner of Poto, to put in a hydraulic installation. Two monitors were installed and work was commenced. The results obtained were excellent, but since the resignation of Mr. Meyers the management has been entrusted to men who have had little experience in the practical operation of a hydraulic mine. There never has been an adequate supply of water available for the proper working of this deposit, nor has there ever been, until lately, any serious attempt at endeavoring to provide a sufficient water supply to work for even as much as nine months in the year. It has always been assumed that this enormous gravel property was above the existing watershed, and the successive managers, accepting this as a fact, were content to work with whatever water was available during the wet season. Two years ago an Argentine company secured an option upon this property and sent engineers to verify the gold content and, if possible, to find an adequate water supply. The result was satisfactory. A supply of water equal to 1500 miner’s inches was discovered, and although the bringing in of the water will be a costly undertaking, yet the gold value discovered was sufficient to warrant the expenditure.

The district of Poto is bounded on the east and northeast by a chain of snow-clad hills, which are known as the third Cordilleras of the Andes, and which is the eastern boundary of the great plateau of Titicaca. The principal rock in this range is slate. The mountains rise to a height of from 18,000 to 20,000 ft. above sea-level. The formation is intersected by innumerable quartz veins, many being rich in gold. During the glacial period the Cordilleras were extensively eroded and the disintegrated mass or moraine now forms the auriferous deposit of San Antonio de Poto. This ground-mass or moraine is composed of small boulders of slate, quartz, granite, porphyries, and sandstone, held together by a cement of finely disintegrated slate and clay, and resting on a bedrock of slate, through the whole of which, from surface to bedrock, free gold is disseminated.

In extent the property is 6000 metres (3.73 miles) long, 1000 metres wide, and 40 metres deep, and contains approximately 240 million cubic metres of gravel (1 cu. m. equals 1.3079 cu. yd.), the average of which is estimated to be 25 cents gold per cubic metre. Large quantities of gold have been won from this property, but the gravel washed in the past has been insignificant, and has hardly affected the value of the property. There are several exceedingly rich pay-streaks...
or nuggets, running through the deposit, but the gold is quite evenly distributed throughout the whole mass. There is no barren gravel, and consequently there is no overburden to be removed before getting into 'pay dirt.' Some of the gold is coarse, nuggety, and flaky, small nuggets weighing up to half an ounce being frequently found, but by far the larger proportion of the gold is in a fine state of subdivision, though not as fine as that called 'float gold.' The gold is very pure, and is purchased by the Peruvian mint at the equivalent of $20 U. S. C. per ounce.

The work actually in progress consists in attacking the south rim of the deposit with two monitors having 4-in. nozzles, working under a head of 125 ft. for as many hours per day as the water-supply will permit, and sluicing the ground broken through a flume having a grade of 6%. This flume is 160 metres long, and is constructed of 1 1/2-in. timbers, which are much worn and generally in a bad condition. In section it is 4 by 2 ft. The paving is of stone, and the flume is laid from 15 to 20 metres above the bedrock. There are no appliances for the removal of boulders or the larger stones, which, if too heavy to be carried away by the Indian workmen, are left where they are, and are always a source of trouble as the work progresses. How profits have been made on the work in the past is beyond comprehension, as everything is done by hand labor; stones that should be sent down the flume are carefully carried out on the backs of Indians, and deposited on unworked ground. Even the trucks in use are not self-tipping and have to be emptied by hand.

The present water supply partly comes from Lake Comuni, which is at the foot of the glacier of the same name, and partly from the melting of the snow in the wet season. The water is impounded in the reservoir Sillacunca, and from here the water is conducted by a well built ditch, having a mean grade of 1 in 300, a distance of 2800 metres to the pressure-box, which is 125 ft. above the monitors. A large proportion of the present water supply is lost through seepage and evaporation, and the pipe-line is leaking at every joint. A new water-supply has been obtained, about 18 miles from Poto, and a quantity equal to 1500 miner's inches has been assured. The cost of conducting this water will be considerable, as there are two wide and deep depressions to be crossed, which can only be done by siphons.

The climate is severe and cold, but remarkably healthy, and although Poto is situated above the line of perpetual snow the water never freezes. There is no actual rainfall, but heavy falls of snow are of daily occurrence. The entire absence of rust is noteworthy, consequently the iron piping used for the water-main continues in good condition for years.

From Molleado, the southern port of Peru, trains run daily to Arequipa, and thence to Juliaca and Puno. It is advisable to spend a day or two in Arequipa, which is at an altitude of 8000 ft. above sea-level, before proceeding to Juliaca, so as to accustom oneself to the rarified atmosphere, as from here onward it is one long climb. At one point, Crucero Alto, the railroad reaches a height of 14,668 ft. above the level of the sea. From Juliaca there are several roads to Poto, either by way of Tirrapa, thence along the Santo Domingo road, lately constructed by the Inca Mining Co., to Crucero, and then across to Poto. The shortest route, however, is from Juliaca to Huancané, thence to Cojata, and from there to Poto. The journey from the railroad to the mines takes about three days, and is made on muleback. This route is certainly the least trying, as there are excellent accommodations for travelers.
MINING ON THE SETENTRION.

Written for the Mining and Scientific Press
By Mark R. Lamie.

Imagine yourself working over a drawing-board, puzzling your tired brain with details of piping, fittings, tanks, and valves. Then get a wire reading as follows: "All right; be here Tuesday." Immediately is conjured the vision of a delightful ride through cool pine forests and grassy valleys, crossing mountain torrents and rugged ranges, the trip pleasantly broken by several nights of camping on streams alive with trout and frequented by game ranging from quail to bear.

The little short-line railway that stretches its fingers up the valleys of the western mountains is mildly irregular in its movements. The day we went out, the first pay-car in many months was hooked to our train. The accounts were closed to within five months, but as the boarding-house and store accounts were subtracted to date, many an Indian was told, when he asked for his pay, "Your account nearly balances; you owe the company only twenty real silver." It is a good way to help them save their money! Construction work on the road is almost at a stand-still while efforts are being made to raise money for the completion of gaps. It will be the scenic road of the continent. In many places, where deep canyons have to be crossed, the advance of one kilometre is made at the expense of 20 kilometres of rails. There are places where the precipice drops 5000 ft. We reached the Barranca de Cobre at lunch time, and, in spite of our anxiety to go ahead, we halted to absorb the magnificent view. The rain had just stopped, and the sun shone on the vivid green of the tropics contrasting with the grays and reds of the soft turf and sandstones. Small clouds formed far down in the branches of the canyon, rose rapidly in the warm currents of air, only to dissipate as they approached the rarer and drier elevation upon which we stood. Ridge after ridge that would otherwise have been merged in the range miles away was brought out clearly by these glistening mists. In the summer, when the bottom of the canyon is like a fiery furnace, the draft over the divide where we stood is continuous and strong, so strong that hats or clothing thrown over the precipice are returned with interesting regularity and precision. Down in this canyon is a copper mine that is said to have reserves of ore equivalent to the whole western plateau. The mine is at the bottom, and if the ore reaches to the top, Butte miners might as well take a holiday.

During the winter this trip is a cold one. A 'tenderfoot' of the party noticed that the Tarahumari moccasins had no blankets and only thin clothes. Kinder than the rest, he insisted on giving the Indian one of his heavy blankets, saying that although he himself would be cold without it, he would not be able to sleep at all with the poor Indian suffering! The Indian took the blanket, watched the others roll up theirs, finally rolling up his for a pillow, and apparently slept comfortably! Then Mr. B. was mad! He could not sleep on account of the cold, while his companions could not sleep on account of the warmth of his language.

After our several days of travel, we reached the Setentrion river, climbing down a steep trail to the bottom of the canyon, over half a mile deep. The river is called Setentrion where it passes that place, but it is called the Santa Barbara, the Rio Plata, and the La Guasa, besides several other names, at different points, so that a traveler in Mexico must usually know a dozen names for each river. This one has cut deep into the plateau and, with its tributaries, has opened up possibilities for prospectors. One extraordinary exposure of ore occurs near the old, almost deserted, town of Setentrion. It is spoken of as "the sixty acres of ore". The hanging wall of a vein has been eroded, actually exposing 60 acres of silver ore on the slope of the mountain. The ore has an average value in silver of only about 10 per ton, much too low to be profitably handled in that neighborhood.

The mines of Setentrion are very old, having been worked in the times when each was a law unto himself. It is told that a former owner, being considerately in debt to the merchants of Alamos, was reported to have uncovered rich ore. Whereupon the Alamos merchants sent an attorney to visit Don Luis, in an attempt to secure the mines for the debts. The old gentleman was pleasant to his visitor even after knowing the object of the visit. Among other places of interest was an immense boulder, in which it had pleased his fancy to carve a tiny jail, fitted with barred doors in true dungeon style. Don Luis escorted the lawyer into this place, then quietly closed and locked the door from the outside. "Now," he said, "I am ready to discuss the matter of my debts. Inasmuch as you have power-of-attorney, I desire a full quittance of my debts. The mine is in bonanza, and as fast as possible I shall pay the accounts, but I do not like legal entanglements." It is said that the attorney promptly agreed that this was a good scheme. Buried treasure has frequently been found in this neighborhood. Two simple natives of Chihuapa found a large case of gold, and to avoid paying 5 per cent to the Government, told a learned friend of their find and asked his advice as to the best method of disposing of the treasure. They told him where it was, and he promised to take care of it. This he did, or at least, they think so! Owing to bandits, wars, and the generally unsettled condition of Mexico in years past, much treasure has been buried. On a certain night in May—I decline to give the exact date—all buried treasure glows with a strong unearthly light, and those lucky enough to know the date spend that night searching for wealth ready made. If the treasure consists of placer gold it will have increased a regular amount each year—grown, in fact—but plate, coin, or other metal which has been melted, of course, does not grow. On our way out one of the party noticed a clump of pines a little way off the trail, apparently planted regularly, and in its midst a square, covered with stones. Upon pounding the spot with a rock, it certainly sounded hollow, but as we had nothing but knives to dig
with the excavation of this treasure was finally postponed until the next trip.

We also saw a limestone cave where the Indians, during an epidemic of black smallpox, had taken the dead, and the dying also, in order to stamp out the plague. It happens that lime is much needed in a camp near there for use in cyanidation, but this cave is let severely alone. And speaking of limestone, the limes of Mexico are rarely pure, yet for strength they seem to be unequalled by anything but cement. Near Setentinión was a masonry bridge, now fallen, but one of the piers that rested on a smooth boulder is still in place, though the boulder has moved from its original site. The pier now stands at an angle from the vertical, and is subject to the full force of the violent floods typical of this region, behaving as though it were a part of the boulder.

These Violent Western rivers have cut through the tufa and exposed a network of veins which could not be found were it necessary to pierce the capping. One mine, discovered by a peon who was ‘gruil-staked’ by two Mexican rancheros, produced a shipment of $55,000 from the cropping. The peon took his first hundred pesos and drank himself out, so the ownership became invested in the two men. The prospect was offered to an American representative of capital looking for mines, not prospects. The American advised the owners to develop, which they did. Afterward, the former took over the property, and is now mining about 70 tons of $100 ore, out of which payments on the mine and on the new reduction plant are easily made. To show upon what small things a fortune sometimes hangs, an incident of the first trip of the purchasers may be related. The owner of the mine, figuring on the rate at which he himself traveled, perhaps also with the idea of minimizing the hardships of the trip, assured the Americans that the journey would require three days. After three hard days the mine was "Ahí, no más!" (just there), until the new-comers became suspicious. On the fifth day he assured them volubly that they would surely arrive before noon. He was then assured that at noon they would most certainly back-trail. At noon the mine was in sight.

On the trail from the Río Plata mines we passed hundreds of mules loaded with plates for the vats of the cyanide plant. The plates are awkward loads and are particularly dangerous. The freighters make a wooden frame, which is tied securely to the plate with thongs. Then the roping of the load to the mule is made fast to this frame. The plates flop about, on the trail, and their sharp corners are so many deadly weapons. Rarely does a pack-train get in without injured animals. My own saddle-mule, in passing a train on a narrow trail, was cut three times in as many seconds. The freighting of these plates costs $12, which is slightly more than the cost of ordinary loads, though the plates are lighter. They are limited in size to 4 by 6 ft., and the curve adds to the difficulty of packing. It takes a strong energetic man (and a strong vein of ore) to propose and carry out the building of a reduction works under such conditions. Many difficulties are overcome in get-

Alamos.

A Railroad Terminus.
each shaft and attempted to drag five to the mine. As fast as a wheel broke, another was cut from the adjoining timber, so most of his time was spent making wheels. Upon looking at the trail one would promptly say that the transportation of shafting this way was impossible, yet he succeeded in getting half way before giving up the contract. The best way to transport the heavy pieces is to see a neighboring Indian chief and arrange with him for carriers. He uses much persuasion and authority, with a little money, to secure relays of ten or more for each shaft. In this way they make five miles per day, which makes the freight for one shaft amount to $550. One company tried to use pipe for shafting, but as this has been replaced with solid shafts, the experiment could not have been successful. Everything heavy must be sectionalized where possible. I remember at one time, during sickness in camp, the doctor insisted on having a trained nurse. She was fair, fat, and forty, and more than a safe load for one mule, so—well, it was not possible to sectionalize!

Governor Shepherd is credited with offering to pay for a piano for his staff in Batopilas, if they would pay the freight. It was carried by hand the entire distance from the then terminus of the railway, and, of course, the freight was much more than the first cost. At one time an enthusiastic party of ladies, prospective investors, journeyed from New York to Batopilas. Joslyn, who was the best-looking man in camp, besides being quiet, dependable, and widely experienced, was detailed to escort the party from the railway to the mines. This would seem to be an easy and pleasant job, but appearances are often deceiving. Hardly any of the ladies had ever been on a mule before. Each thought she had the hardest-riding animal, the first day out. Anything was an excuse for a stop the second day. If a pretty stream was crossed, nothing would do but the tent must be set up over it, and all hands took a bath. A field of wild flowers was good for an hour’s delay, and after orchids were recognized the party hardly moved. It is said that the party was barely started some mornings by noon. One lady insisted on riding Joslyn’s mule, though warned that the animal was tricky. She was no more than mounted when the mule turned and bit her leg. Even then she was not satisfied, insisting that Joslyn just knew the mule would do that! He finally landed them at the mine, his hair turned gray. He hastened to resign before the party was ready to return.

Such was the story as I got it on the trail, and I must add that I believe it, but if any of the party will advise me of any errors, I shall be glad to make the proper corrections. It seems a difficult trip for women. at the best, though many make it. Where riding a mule is out of the question, it is only a little more trouble to provide relays of carriers and travel in a chair. The rate of travel is nearly if not quite as fast, and the journey is made in much more comfort. Even babies make the trip. As a suggestion conducive to comfort in traveling, I would advise mining men who expect to journey much in Mexico to arrange for children in pairs, as otherwise the question of packing the odd one is sometimes difficult. The two balance each other nicely in panniers on each side of the mule, while the odd one must be over-balanced by a bed or grub-box or under-balanced by a valise or a camera.

**Training of apprentices** is one of the most important problems with which modern industrialism has to deal. A number of railroad companies, as explained by William Menkel in the *Review of Reviews*, have established systematic courses of study for young men, to which older workmen are, in some cases, also admitted. This work has now passed the experimental stage. In the night school conducted by the Union Pacific in its Omaha shops, attendance by apprentices is compulsory. A regular three-year course is mapped out, including arithmetic, elementary mechanics, and mechanical drawing. The Omaha Public Library has established a special branch at the shops, containing books on mechanics and engineering, to which the men have free access. As soon as the boys finish the course properly they are put at responsible work. A similar apprentices’ night school is maintained by the Oregon Short Line at Sparks, Nevada, under supervision of a professor from the State University. A feature of this school is the time-credits allowed to the boys for punctual attendance and proper interest. This credit amounts to 30 days for each year, and is applied on their apprenticeship. In its transportation department the Oregon Short Line trains young men as brake-men, under the care of experienced crews. The students are drilled in the methods of handling trains, and are required to study the rules and regulations of the operating department. Their progress is carefully watched, and when proficient they are recommended to the train-masters, by whom they are thoroughly examined before qualifying as regular brake-men. Although the services of these young men are not of much value while they are learning the business, the company pays them sufficient wages to support them during their apprenticeship. The Grand Trunk road has had an apprenticeship system in successful operation for a number of years. Applicants for an apprenticeship must first pass examinations to prove their moral, physical, and mental qualifications for service as a mechanic. They are then indentured to the machinist’s trade for five years, or to the blacksmith, boilermaker, or other trades for four years. Five cents per day is deducted from the wages of each apprentice, and the total sum is returned to him at the end of his apprenticeship, together with a bonus of $25 if his services have been satisfactory. Examinations are held each year, and prizes are awarded. Upon completing their apprenticeship the young men receive certificates officially setting forth the fact that they are competent mechanics. The Grand Trunk also supports six scholarships at McGill University, where there is a course in transportation. These scholarships are open to the sons of employees as well as to the younger men in the employ of the company, and are eagerly sought for, two usually being awarded each year.
STAMP MILL PRACTICE ON THE MOTHER LODE.

Written for the Mining and Scientific Press
By Alex Chalmers.

The ores of the Mother Lode in California, as a general rule, are low-grade, and in addition to good management, require the most efficient machinery to work them to a profit. Any improvements in methods or machines that tend to reduce the costs of mining and milling mean ultimately a greater industrial activity and a larger yield of the precious metal. On the Lightner mine, at Angels Camp, we have, within the past year, had some experience in milling that has been profitable to us, and should be of interest to others. The Lightner mine is about in the centre, north and south, of the Mother Lode, and the ore is typical of this great belt.

On October 30, 1905, our entire plant above ground was destroyed by fire. Previous to this date we had been operating successfully what we considered the most modern stamp-mill in California. After clearing away the ruins, we set about to duplicate the entire arrangement, and on February 16, 1906, we again had our 40-stamp mill in active operation. The reconstructed mill did fully as good work as the mill that was burned, crushing every day of 24 hours, about 200 tons of ore, or an average of 5 tons per stamp. In 1907 our ore reserves increased to such an extent that we decided to augment our milling capacity by adding 20 stamps to the "old mill" of 40 stamps. This new mill began crushing on November 15, 1907. The entire iron-work was supplied to us by the Angels Iron Works, and was designed by the manager of that foundry, D. C. Demarest.

Soon after dropping the new stamps we were agreeably surprised to find that it handled considerably more ore per stamp than the "old mill"; that the loss in tailing was no greater, that it required no more power, and that the percentage of amalgam recovered inside the mortars was larger than in the "old mill". Among other interesting features, it may be mentioned that this mill requires no more water, either for battery or for concentrators, and that the life of both the shoes and the dies is prolonged. This new plant is crushing from 10 to 15% more ore than our old mill, with no expenditure per stamp for power, water, and labor, and with less cost for wear and tear.

Some of the details of the new mill are as follows:

The stamps weigh about 1000 lb. each, and are given a drop of 7 inches, at a speed of 106 drops per minute. The height of discharge above the die is 7 1/2 in., punched screens of 30 mesh are used, and each battery has 308 sq. in. of clear screen-opening. The shoes are made of chrome steel and Pennington hammered steel, weighing, when new, 181 lb., and when worn out, from 25 to 30 lb. They last about 10 months. Semi-steel dies are used, 5 1/2 in. high, weighing 82 lb. when new, and about 30 lb. when worn out, after a service of 8 months.

The mortars are known as the 'close pattern', and there is no surplus room, either between the stamps themselves, or between the stamps and the linings of the mortar. The stems are held rigidly in place and in alignment, and are made more efficient as crushers by a patented iron guide known as the Pacific Battery Stem Guide. The mortar-blocks are of sugar pine, resting on concrete foundation.

Each battery is equipped with 88 sq. ft. of copper plate, 2 1/2 oz. silver per square foot. These plates are arranged in lines 2 ft. wide by 22 ft. long, all on a grade of 2 in. per foot. Three 4-ft. Frue vanners take the pulp from each 5 stamps. Each battery requires a water-supply of 8 gal. per min. and each concentrator a water-supply of 1 gal. per minute.

The mill is driven by a 50-hp. induction motor. The 20 stamps, 12 Frue vanners, 36 ft. of 4-in. mill line-shafting, and 34 ft. of 2-in. concentrator counter-shafting consume 40 horse-power.

The tailing is sampled automatically, showing an average loss, on ore ranging from $3 to $6 per ton, of 20 to 25c. per ton of ore crushed. This loss is practically the same in the old and the new mill. Inside the mortars of the old mill we recovered about 20%, while in the new mill this percentage never drops below 25% of the assay-value.

Ordinarily it requires but six men to look after the entire 60-stamp mill. There are times when chips are coming freely from the mine; then two additional boys are required to keep the mortars free from these wood particles. It may be mentioned that our screen-frames are all equipped with a pocket, provided with a little hinged door, so that the mill-man can get his hand inside the mortar without removing the screen-frame. This device saves time on account of there being so many chips in the ore.

Our labor cost for milling averaged about 22½c. per ton with the old 40 stamps, while with the entire 60 stamps this cost ranges from 20 to 15c. per ton.

The Belgian method of tunneling through soft ground was first employed in 1828 in excavating the Charleroy tunnel of the Brussels-Charleroy canal, in Belgium. The distinctive characteristic of the method is the construction of the roof arch before the side walls and invert are built. The excavation therefore begins with the driving of a top centre heading, which is enlarged until the whole of the section above the springing lines of the arch is opened. The roof arch is then built, and is, of course, supported by the unexcavated material below. This material below the springing lines is excavated by taking out first a central trench to the depth of the invert, and then by removing the two parts on either side. As these side parts have to support the arch, they must be excavated in such a way as not to endanger it. Hence, at intervals along the central trench, transverse trenches about 2 ft. wide are excavated on both sides and struts are inserted to support the roof arch, and masonry which has probably been built by that time. The completion of the excavation consists in widening these transverse trenches.

Consumption of lumber in the United States in 1850 was 250 ft. per capita, and 480 ft. in 1907.
MINING AND METALLURGICAL PATENTS.

SPRINKLING-CAR FOR MINES.—No. 905,950. Peter Doney and Alexander P. Cochrane, Monongahela, Pennsylvania.

A sprinkling car of the type described comprising a tank and wheeled trucks supporting same, a pump carried on the top of the car, a gearing connecting the pump with the axle of one of the trucks, combined with a substantially U-shaped sprinkler frame embodying a perforated pipe extending across the top of the tank and in communication with the tank through the pump, vertical pipes communicating at their upper ends with said top pipe, perforated branch pipes projecting longitudinally from both ends of said vertical pipes, the said top pipe having its perforations directed to project the water upwardly and the said longitudinally extending branch pipes having their perforations directed to project the water both laterally and downwardly.

In a device of the class described, a reciprocating table; a projecting breast-board along the rear side thereof; and a series of riffles upon the surface of the table arranged in successive similar groups, the end riffle of each group extending to the mineral discharge edge of the table, the other riffles of the respective groups in length successively toward the corresponding end riffle thereof, all of said riffles being tapered from their inner ends at the breast-board to their outer ends, the said end riffles increasing and the other riffles decreasing in height successively toward the tailing discharge end of the table.

PROCESS OF OBTAINING METALS FROM THEIR ORES.—No. 904,263. Karl Kaiser, Berlin, Germany.

The process of obtaining metals from materials containing oxidizable substances, which consists in heating the raw materials in an electric furnace, then forcing a gaseous oxidizing agent into contact with said heated materials, then forcing a gaseous reducing agent into contact with the heated material, leading off and condensing metals escaping in gaseous form, and running off the liquid metals into molds.

In a drill of the class described, the combination of a drill tube, a shank of less diameter than said tube and adapted to have detachable interlocking engagements with the upper end of said tube, and means for preventing the accidental disconnection of said shank from said tube through the rotation of said shank in either direction.

In a drilling machine, the combination with a bed-plate, and a base pivotally mounted thereon, of a horizontal sleeve mounted to rock in said base, a drill stock joined to said sleeve and extending at an angle therewith, drill operating means carried by said sleeve and drill stock, and a driving shaft having its axis lying in the same plane as the axis of the drill stock.

In a coking oven, the combination of a series of vertical heating flues, a gas canal below such flues, a gas opening therefrom leading to each flue, a series of adjustable dampers for regulating the supply of gas and operable from the front of the oven, and an opening in the oven front through which a suitable implement may be inserted to operate any one of the series of dampers, substantially as described.
A Mine Power Plant.

By GEORGE M. CRAWFORD.

The extension of mining operations over a considerable area of ground is now common in both coal and ore mines. In such instances the generation and transmission of air and electric power assumes new and interesting aspects.

A Standard Compressor.

The power used for mining machines, pumps, drills, hoisting and haulage, ventilation, etc., may be produced: 1, in several independent plants, each with boilers, generator, sand steam or belt-driven compressors; 2, in a central station, with large economical steam units, the air being piped and the current wired direct to the machines; 3, in a central electric generating plant, from which current is wired to sub-stations, where the air-compressors and motors that drive the machinery in each part of the field are erected.

The first plan is now seldom adopted, owing to the high cost of supplying fuel and water to each of several plants, and the duplication of attendants. Further, the system lacks economy and flexibility, because, as the workings are extended, the power lines become longer, more expensive to maintain, and reduce the efficiency of the whole plant. Such a plant can be moved to a new site only at heavy expense for buildings, machinery, and facilities for transporting supplies.

The second plan is more convenient and economical in the production of power, but is wasteful in transmission. It requires long air-lines of large size and electric wires of large diameter to carry a low-voltage current suitable for machine operation.

The last plan represents the latest practice. It involves the production, in a central plant, of high-voltage current by steam or hydraulic turbo-generators. This current is then carried to substations, where it operates air-compressors, fans, pumps, and haulage locomotives. This results in the greatest possible economy of pipe-lines, wiring, attend-

Sullivan Coal Pick-Machine.
Decisions Relating to Mining.

Specially reported for the Mining and Scientific Press.

INJURY TO MINER—CONTRIBUTORY NEGLIGENCE.

A coal miner, killed by the falling of the roof of the mine where he was working, was not guilty of contributory negligence in working under the roof when he knew of the defect in the roof, and voluntarily went under it, unless it was shown that he knew the defective roof was dangerous; it was the owner's duty to prop the roof and make it safe. But under such circumstances there could be no recovery where the mine boss warned him of the danger and instructed him not to work under it.

Mascot Coal Co. v. Garrett, (Ala.) 47 Southern 149, June, '08.

MINES—CONVEYANCE AND LEASE OF MINERALS.

A clear distinction exists between a grant of a right for a term of years to take mineral from certain premises, coupled with the right of ingress and egress, and the direct sale of such mineral in place; the latter amounts to a conveyance of an interest in the land itself, the former does not, and is not taxable.

Board of Supervisors Hancock County v. Imperial Naval Stores, (Miss.) 47 Southern 177, June, '08.

MINING LEASE—Lien for Royalties—Fixtures.

A mining lease gave the lessor a first lien on all improvements to secure the payment of royalties on coal mined; and giving the lessee the right to remove the building, machinery, etc., subject to the conditions of the lease. Under the lease it was held that the building and machinery were not fixtures, and the lessor had no interest therein except the lien for unpaid royalties.

Cherokee Construction Co. v. Bishop, (Ark.) 112 Southwest 159, May, '08.

INJURY TO MINER—MINING MINE SAFE.

A carman in a gypsum mine, immediately prior to his injury, had been ordered to remove from the foot of the shaft a lode of props with which to support the mine roof, and such props were being unloaded and delivered to the prop setter when the carman was killed by the fall of a portion of the roof. Under these facts it was held that the carman was not engaged in making the mine safe at the time of his death, and, having no knowledge of the danger attending the failure to properly prop the mine, the mining company was held liable for failing to afford him a reasonably safe place in which to work.

MINING CLAIM—Failure of Co-owner to Contribute.

If one of several co-owners fails to contribute his proportion of the required work or make the necessary improvements, the other co-owners who have done the required work may give such delinquent notice, and after the stated time if such delinquent fails or refuses to contribute his proportion of the expenditures, his interest in the claim shall become the property of the co-owners. But the question of the performance of assessment work sufficient to prevent the forfeiture of the interest of a co-owner is one of fact for the jury to determine.

INJURY TO WORKMAN IN QUARRY—CONTRIBUTORY NEGLIGENCE.

A workman injured in a quarry by rock falling from a wall cannot recover on the ground of negligence of the boss who sent him to shovel loose rock, or 'sprawl', near where there was loose rock in the wall which was likely to fall, and which he could have discovered by the exercise of diligence.

Alabama Coal Co. v. Hammond, (Ala.) 47 South 246, June, '08.
EDITORIAL.

ASSSESSMENT WORK on mining claims is a timely subject near the close of the year, and we are glad to be able to publish an authoritative article by Mr. William E. Colby, who is associated with Lindley & Eischoff. He gives some good advice in a way that cannot be misunderstood. If you have not done your assessment work, hasten to do so, and do it honestly and intelligently, so that the law may be fulfilled and the mine developed.

WE PUBLISH a lengthy extract from the President's message, but the extract is only a small fragment of the last pronunciamento sent by Mr. Roosevelt to the Congress of the United States. Taken together the messages sent by Mr. Roosevelt to the Congress constitute a formidable and deeply interesting mass of writing. These messages have been widely read by the plain people and they have done much to mold public opinion. But they do need editing. If Mr. Roosevelt had a trained précis writer at his service, his communications would gain in force; they are too diffuse. The recent exchange of compliments with the New York Sun illustrates this. Mr. Roosevelt wrote a long invertebrate letter to a friend attacking the Sun; we were glad to see that attack, for the Sun is one of the most powerful of undermining and disintegrating forces in America. But the letter was too long. Mr. W. M. Laffan replied tersely, insidiously, effectively. Right was shamed and wrong cackled.

AN EVENT of world-wide interest was celebrated in connection with the exercises of the Mining Congress at Pittsburg on December 3. This was the opening of a national testing laboratory for scientific investigation of causes and means for prevention of mine accidents. At the ceremony Mr. James R. Garfield delivered a sympathetic address, accentuating the need of a more tender regard for the protection of human life in the work of producing the nation's mineral wealth. This sentiment was emphasized by Mr. J. A. Holmes, who said, "the consumer does not want to burn coal stained by the blood of the butchered miner. The American people are willing to pay more for their coal. Pittsburg district is selling its fuel too cheaply. We pay 75 cents per ton for coal here; in Europe it costs $2 per ton. Let us have higher-priced coal and safer mining." Of course 75-cent coal, or even $1.15 coal, which is a more common figure for run-of-mine, at Pittsburg, becomes $2.50 at New York, and $3.25 at Boston. We do not refer to Western prices, which have made the metaphorical 'black diamond' a stern reality. The fuel will undoubtedly stand an increase of cost at the mine-tipple for the sake of safety, but the transportation companies need to readjust their
schedules to cheapen this great necessary of life to the consumers. This happy condition will come about only when the recommendations of the President for placing all railway matters in the hands of the Interstate Commerce Commission are enacted into law.

**Mining Congress.**

The eleventh annual session of the American Mining Congress recently held at Pittsburg was a useful convention. As it becomes older the Congress gains in dignity; the undesirable elements are being shed as it progresses onward; there is less wind and foam, and more real advance. We are pleased to note that this last session was devoid of papers of technical or scientific character, for the Congress is no fit occasion for the reading of such papers. On the other hand, addresses calculated to educate the general public were not wanting, notably those by Mr. James Douglas on the influence of transportation on the mining industry, by the Director of the Survey on the 'Distribution of the Nation's Wealth,' and by Mr. A. H. Brooks on 'The Mineral Resources of Alaska.' Such addresses would give value to any meeting. Although of less general interest, the papers by Mr. G. W. Traer on 'Conservation and the Coal Industry,' and that on the 'Northern Appalachian Coalfield,' by Mr. I. C. White, were of even more immediate application than the addresses that preceded. Mr. White's paper afforded an excellent illustration of the wide economic importance of certain features of geological work and was well designed to arouse public interest in the application of science to industry.

The meetings were enlivened by one or two debates. It was expected that the opponents of the Forest Service would have something to say and that Mr. Gifford Pinchot's friends would be eager to make reply. Fortunately, the good sense of those in control has resulted in the decision to leave the matter to the special committee, of which Mr. A. G. Brownlee is chairman, and a conference with the Federal officers will be held shortly at Washington.

We note with interest that Mr. W. R. Ingalls, as chairman of a special committee on revision of the mining laws, recommended greater uniformity in the statutes of the different States and was able to announce wide-spread interest in such useful reforms. The onslaught upon the smelter trust by Mr. E. A. Colburn, of another committee, fell rather flat because the audience before which he spoke was interested in coal mining. While we appreciate that causes for irritation exist, we cannot see that anything useful can be done by general charges; to be effective, specific facts and figures must be adduced.

At this session there was no need to urge the creation of a National Bureau of Mines, for that is now assured. Senator Dick, who is chairman of the Senate Committee on Mines and Mining, promised that the bill establishing the Bureau would be passed by the Senate before March 4. Thus the American Mining Congress has achieved one of the main purposes for which it was organized. We tender our congratulations to the President of the Congress, Mr. J. H. Richards, who for six years has worked with a rare mingling of judgment and enthusiasm for this recognition of the mining industry. He deserves much credit for his public spirit; and it is obvious that his motives were wholly disinterested, for he has refused to allow his name to be used as a candidate for director of the Bureau of Mines. One of the memorable incidents of the meeting at Pittsburg was the renouncing by Mr. Richards of any ambition for the office and his cordial endorsement of Mr. J. A. Holmes, now chief of the Technologic Branch of the Geological Survey. It is likely that Mr. Holmes will get the appointment. He is a hard worker, a man of good sense, and much tact; in many ways he is particularly well fitted for the post. He has taken prominent part in several sessions of the Congress and has used the opportunity worthily to become known to those behind the movement for a Bureau. Thus the Congress will be responsible both for the Bureau and for its chief; this will enhance the importance of its annual conventions and enlarge its field of usefulness.

**A Tariff Commission.**

In business let us be exact, systematic, scientific; in government let us adhere to the primal independences of the untutored past, and revel in the joys of inexactitude, chance, and special privilege. Such is the logical deduction the observer is forced to make from the persistence of numerous rude policies in our system of government. The public retains more of the child in its collective character than the individuals that compose it. Like a child it shirks responsibility; like a child, dreaming of gifts from fairy god-mothers, it courts opportunity from fortuitous happenings. It recoils from detail in contentment with generalities, as plainly appears from the fact that it obtains nothing better from the irresponsible press, and demands nothing conclusive from official sources. If proof of this were demanded it might be found in the fact that man has not yet reached a stage of development where he is willing to face the needs set forth in the national budget and provide for them as the manufacturer would provide for his pay-roll. The indirect tax is perhaps a necessary expedient in the present state of the world's political evolution; but it is iniquitous in principle; it demonstrates a preference for the dark instead of the light, in which more readily breed the microbes of corruption.

A better example of haphazard unscientific legislation could not be found than the tariff. Every item has been placed on the list in deference to the wishes of interested groups of men. Analysis there has been none; the investigation by committees has consisted in taking ex parte testimony, not in thorough determination of costs and conditions of production such as a man would deem necessary in his own business. In all countries and in all times protective tariffs have been unscientific. They have protected only one party to the contract by absolutely prohibiting foreign competition. In the days of 'good Queen Bess' they were more honest about it than we. The copper industry of Great Britain was encouraged
by a law that fixed the penalty of death for import-
ing that metal in any form. It was drastic, but
effective; it was unblushingly barbarous in its grim
threats against competition; it was, of course, bar-
barous in its disregard of the principle that protec-
tion may foster industry without abandoning the
people to monopolistic robbery. There is a balance
to be struck between the benefit that a protected in-
dustry affords to the commonwealth through pro-
viding a market for materials and work for other-
wise idle hands, and the compensation the public
may justly grant in the form of enhanced price under
cover of a customs duty for the article produced.
To sift the facts regarding costs of production in
different countries, and the average costs of distri-
bution, to weigh the value to the community of the
industries that protection would create, and to fix a
tariff giving an advantage commensurate with this
estimated return, would be scientific; it would be
business-like; it is feasible.
Mr. Taft is committed by his utterances during the
presidential campaign to a thorough investiga-
tion of the schedules, with the avowed purpose of
reducing those found to be excessive. If the tariff
fortifications are shaken by a few more bombs like
the one just exploded by Mr. Carnegie the country
will become so insistent upon tariff revision that
Mr. Cannon and all the Trust-guardians on the Ways
and Means Committee cannot prevent an exciting
congressional session. Mr. Carnegie has tardily an-
nounced, what has long been an open secret, that
steel is produced in America today more cheaply
than elsewhere in the world, and that even the labor-
cost per ton is lower, despite the higher wages paid.
Thus has the workman become more than ever the
mere brain for directing wonderful mechanisms, dis-
placing the labor of a multitude of hands. Mean-
while the Ways and Means Committee is giving
audience to an army of petitioners for increase of
duties. The sugar producers never find the tariff
quite sweet enough; this hunger is so great as to
make proserlytes of Louisiana Democrats; it pro-
motes a love-feast at which widely separated and
strangely discordant interests sit complacently as
fellow-banqueters. The cotton manufacturers of
New England and of the Southern States have been
at war for years. The New England gentlemen have
been zealous in detecting the mote of child-labor in
the eye of their brother cotton-spinners of the South,
and there has been exchange of uncomplimentary
remarks concerning their respective moral attitudes,
but when it comes to the tariff they are in sweet ac-
cord. Mr. F. E. Lippitt, of Providence, Rhode Island,
and Mr. E. E. Tompkins, of Charlotte, North Caro-
lina, voice the unanimous opinion of the American
Cotton Manufacturers’ Association, that the duty on
cotton cloth must be retained, and that the rates on
cotton yarns should be increased. We are even told
that cotton-manufacture is still an infant industry
in the United States. On the other hand, the soap
manufacturers are besieging the Committee with
demonstrations of the iniquity of the duty on tallow,
coconut oil, soda ash, and other alkalis, clamoring
for what we may call rear-end protection.

Manifestly an investigation of the schedules in
this manner can lead to no effective remedies. The
uncertainties introduced are detrimental to business
in high degree. That is why the mass of voters is
content to suffer iniquitous tariffs so long. The dis-
aster incident upon a great upheaval of revision
makes the country prefer the evils that we have
rather than fly to those of which we know not. This
is all because the method is irrational, unscientific.
Mr. Carnegie would have helped forward true re-
form more effectively had he insisted upon the appli-
cation of a sliding scale of customs duties, under con-
trol of a permanent commission. By his showing, the
operation of such a system would extinguish the duty
on iron and steel, while the industry would remain
impregnable. A rational administration of the tariff
would have no terrors; it would not involve the ex-
tricities of life and death for business enterprise;
would not unsettle industry as haphazard revision
must inevitably do.

There can be no argument against the establish-
ment of a permanent tariff commission except that
it will lead to systematization, and lessen the power
of a few to absorb the earnings of the many. Had
not the people been so steeped in reverence for the
traditions of whimsical government the demand for
rational methods would long ago have displaced such
an anachronism as our present tariff-blight upon an
intelligent nation. Democracy has per petuated a
principle of imperialism, substituting the will of the
people for the will of the autocrat. It takes time
to reach the elevated plane where the reason of the
people shall govern through the application of wise
scientific methods. The work of the Interstate Com-
merce Commission has shown the possibilities of
permanent organized effort to control delicate and
difficult affairs by adjustment responsive to varying
conditions, and has demonstrated the gain to the
public in such procedure over reliance upon occa-
nional patch-work legislation. From this the exten-
sion of the idea to the tariff is a natural step. No
protective tariff is correct in principle or in appli-
cation that does not benefit the entire community;
manifestly a rigid tariff schedule, despite annual
 tinkering to repair it, can not fit the needs of a pro-
gressive nation. It must be subject to modification
in respect to altering circumstances under the law of
supply and demand at home and abroad, and such
flexibility can be given only through a well organ-
ized bureau under control of a representative com-
mission with plenary powers.

The question between the policies of protection
and free-trade need not influence the discussion of a
practical mechanism for dealing with the concrete
problem. A country as vast as the United States,
and yielding so wide a range of products as to make
it a little world in itself, will not speedily throw
wide its gates. But we need protection not only
against the evil features of a Trust-generating tariff,
but against the disturbance of reckless revision. It
is time to modernize even the tariff, to make it a
rational instrument, administered in a systematic
scientific manner, in the interest of all the people—
as it can be.
BY THE WAY.

The President in his message to Congress depicts the evils of deforestation graphically, as follows:

There are small sections of our own country, in the East and in the West, in the Adirondacks, the White mountains, and the Appalachians, and in the Rocky Mountains, where we can already see for ourselves the damage in the shape of permanent injury to the soil and the river systems which comes from reckless deforestation. It matters not whether this deforestation is due to the actual reckless cutting of timber, to the fires that inevitably follow such reckless cutting of timber, or to reckless and uncontrolled grazing, especially by the great migratory bands of sheep, the unchecked wandering of which over the country means destruction to forests and disaster to the small home makers, the settlers of limited means.

Thanks to our own recklessness in the use of our splendid forests, we have already crossed the verge of a timber famine in this country, and no measure that we now take can, at least for many years, undo the mischief that has already been done. But we can prevent further mischief being done; and it would be in the highest degree reprehensible to let any consideration of temporary convenience or temporary cost interfere with such action, especially as regards the national forests, which the nation can now, at this very moment, control.

All serious students of the question are aware of the great damage that has been done in the Mediterranean countries of Europe, Asia, and Africa by deforestation. The similar damage that has been done in eastern Asia is less well known. A recent investigation into the conditions in north China by Frank N. Meyer, of the bureau of plant industry of the United States Department of Agriculture, has incidentally furnished us with striking fashion proof of the ruin that comes from reckless deforestation. Not many centuries ago the country of northern China was one of the most fertile and beautiful spots in the entire world, and was heavily forested. We know this not only from the old Chinese records, but from the accounts given by the traveler, Marco Polo. He, for instance, mentions that in visiting the Provinces of Shansi and Shensi he observed many plantations of mulberry trees. Now there is hardly a single mulberry tree in either of these provinces, and the culture of the silk worm has moved farther south to regions of atmospheric moisture. As an illustration of the complete change in the rivers, we may take Polo's statement that a certain river, the Hun Ito, was so large and deep that merchants ascended it from the sea in heavily laden boats; today this river is simply a broad sandy bed, with shallow, rapid currents wandering hither and thither across it, absolutely un navigable. But we do not have to depend upon written records. The dry wells and the wells with water far below the former water mark, bear testimony to the good days of the past and the evil days of the present. Wherever the native vegetation has been allowed to remain, as, for instance, here and there around a sacred temple or imperial burying ground, there are still huge trees and tangled jungle, fragments of the glorious ancient forests. The thick, matted forest growth formerly covered the mountains to their summits. All natural factors favored this dense forest growth, and as long as it was permitted to exist the plains at the foot of the mountains were among the most fertile on the globe, and the whole country was a garden.

Ruthless destruction of the forests in northern China has brought about, or has aided in bringing about, desolation, just as the destruction of the forests in central Asia aids in bringing ruin to the once rich central Asian cities; just as the destruction of the forests in northern Africa helped toward the ruin of a region that was a fertile granary in Roman days. Short-sighted man, whether barbaric, semi-civilized, or what he mistakenly regards as fully civilized, when he has destroyed the forests, has rendered certain the ultimate destruction of the land itself. In northern China not only have the forests been destroyed, but because of their destruction the soil has been washed off the naked rock. The terrible consequence is that it is impossible now to undo the damage. Many centuries would have to pass before soil would again collect, or could be made to collect, in sufficient quantity once more to support the old-time forest growth. In consequence the Mongol desert is practically extending eastward over northern China. The climate has changed and is still changing. It has changed even within the last half century, as the work of tree destruction has been consummated.

That everything dries out faster than formerly is shown by the fact that the level of the wells all over the land has sunk perceptibly, many of them having become totally dry. In addition to the resulting agricultural distress, the watercourses have changed. Formerly they were narrow and deep with an abundance of clear water the year round; for the roots and humus of the forests caught the rainwater and let it escape by slow, regular seepage. They have now become broad, shallow stream beds, in which muddy water trickles in slender currents during the dry seasons, while when it rains there are freshets and roaring muddy torrents that come tearing down, bringing disaster and destruction everywhere. They wash away or cover in the valleys soil which took tens of thousands of years for nature to form.

In northern China this disastrous process has gone on so long and has proceeded so far that no complete remedy could be applied. There are certain mountains in China from which the soil is gone so utterly that only the slow action of the ages could again restore it.

What has thus happened in northern China, what has happened in central Asia, in Palestine, in north Africa, in parts of the Mediterranean countries of Europe, will surely happen in our country if we do not exercise that wise forethought which should be one of the chief marks of any people calling itself civilized. Nothing should be permitted to stand in the way of the preservation of the forests, and it is criminal to permit individuals to purchase a little gain for themselves through the destruction of forests when this destruction is fatal to the well being of the whole country in the future.
Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. T. Bayliss is at El Oro.
Hiram W. Hixson is in London.
W. Pellet Harvey is on his way to Australia.
James T. Dixon has returned to England from Siberia.
Howard W. DeBois is examining copper mines in Nevada. Claude V. Atkin has an office at 730 Salisbury House, London.
Jesse J. Macdonald is with the American Trading Co., at London.
Thos. H. Leggett and Fred. Hellmann are here from New York.
Thomas D. Murphy was recently at El Oro, and is now in Costa Rica.
D. H. Harboux, of Mexico City, was recently in the territory of Tetip.
W. L. Benedict is expected in San Francisco shortly. He is now in Arizona.
R. H. Bubrown, of Guanajuato, is professionally engaged at Pachuca, Mexico.
Edward L. Depoucoq, of New York, is in San Francisco, on his way to Nevada.
D. E. Blake sails on December 11 from San Francisco for the Philippine Islands.
Falcon Josslin, president of the Tanana Valley Railroad Co., has gone to New York.
A. G. Scyvham is superintendent of the San Roberto mine, at Zacatecas, Mexico.
C. W. Purinton leaves London on December 12 for a short visit to the United States.
S. E. Robins, formerly at the Fremont mine, in Amador, California, is now in Costa Rica.
A. B. Emery represents the American Smelters Securities Corporation at Velarde, Mexico.
Robert Hawkins, Jr., has completed the examination of the Santa Yjitas copper mines, in Chile.
Cecil Pcock has been appointed general manager of the Montezuma mines, in Costa Rica.
F. H. Clarke, manager of the San Cayetano mines, Guanajuato, Mexico, has gone to New York.
C. C. Schinatzeck has resigned as associate editor of the Mining World, and is now at Baltimore.
E. A. Stuart is superintendent for the Guanajuato Development Co., succeeding John Butler, who resigned.
Allen & Colborn, of Denver, have completed the examination of copper claims in Grand county, Colorado.
Hugh Rose, general superintendent for the Guanajuato Development Co., has returned to Guanajuato, Mexico, from New York.
L. D. Mills is at Guanajuato, in the interest of C. W. Merrill, of San Francisco, making experiments with the Merrill precipitation process.
Jos. L. Dazier, formerly of the department of chemistry, in Columbia University, has been appointed manager for the Canadian Behrend Dry Concentrator Company.
John P. Cosono, mechanical superintendent for the American Smelters Securities Co., has tendered his resignation. Mr. Cosgro is at present at the Flat River plant of the Federal Lead Company.
E. C. Trask, general foreman of the Yampa smelter, and C. L. Kramer, chemist at the same plant, resigned on December 1 to engage in the coal business at Salt Lake City, under the firm name of the Wasatch Supply Company.

The special three-months course for mining men begins its eleventh annual session at the School of Mines of the University of Washington, at Seattle, on January 5.
General Mining News.

ALASKA.

The Eagle River Mining Co. is operating with 70 men and is supplying ore to the 30-stamp mill crushing 75 tons per day. The concentrate goes to Tacoma. Work will proceed throughout the winter. B. L. Thane is manager.—New and promising mineral discoveries on McLean's arm, on the southeastern side of the Prince of Wales island, have caused considerable activity. W. A. Thompson has exposed a large ore body on Mallard bay, one and a half miles south of McLean's arm, which contains copper, gold, and silver, the lowest assay showing a total of $12. Ickes & Poison are driving an adit on the arm which is now in 75 ft. and is said to show a good ore body.—Reports from Juneau state that a discovery of very rich quartz ore has been made near Auk bay, which is at the western end of Gastineau channel. The prospectors who made the find are Victor Spaulling, Perry Wylie, and John Childs, the latter better known as Saltwater Jack. The end was made on the southern slope of a ridge running from the mainland out toward the upper end of Douglas island, and distant from Juneau about eight miles, in a westerly direc tion. The gold was all panned, as the quartz in which it occurs has been badly decomposed. It is probable that a big rush will result as soon as the snow has disappeared.

ARIZONA.

GILA COUNTY.

The Live Oak property, a short distance west of Globe, has been leased to H. R. Hovland, of Duluth, president of the Com. Copper Co. The price is said to be nearly half a million dollars and the term of the contract is two years. The orebody is opened by two shafts, neither of them deeper than 150 ft., and by several adits and open-cut. In one of the shafts sulphide ore has been cut, and it is the opinion of mining experts who have examined the property that with deep development it should make one of the big mines of the district.

MOHAVE COUNTY.

J. T. Davis, of San Francisco, who has a bond on the Midnight mine in the Chloride district, expects to equip the property with a milling plant. The Tazawa Development Co. will probably start development on the Gold Giant and other claims in the Cottonwood district.—J. A. Elway is sinking a shaft on his claim at the Gross ranch, near Cerbat.—J. D. Jordan, who has had a bond on the Gold Crown group of mines in the Union Pass district, has transferred his option to Dan S. Richards. The mines are owned by O. D. M. Giddis and Dr. W. E. Sauls. It is the intention of Mr. Richards and associates to begin active work on the mines within the next month and is now getting things in shape to start a camp at the mines.—A strike has been made on the Holy Moses mine, owned by A. L. McKesson about seven miles south of Kingman. At a depth of 63 ft., five feet of rich milling ore has been cut, but owing to the inflow of water and lack of machinery to handle it, work had to be stopped until a hoist can be put on. For a month past Mr. McKesson has been running his little mill one hour a day on ore from the shaft, which nets about $26 per ton on the plates. Drifts have been run on the vein some distance from the shaft and fine ore found. As soon as a hoist is put in the shaft will be sunk 100 ft. further.

PINAL COUNTY.

As work progresses on Woodhury & Lohr's new copper discovery, about 25 miles north of Florence, in the foothills of the Superstition mountains, the prospects are more encouraging.

CALIFORNIA.

MASON COUNTY.

T. L. Oddie, of Tonopah, has taken a bond on the Jim Wright property in the White mountains, 12 miles from Big Pine. Six men are now at work and the ore is to be shipped to the smelter at Keeler. The lease and bond require the sinking of 150 ft. in the present shaft, and a certain amount of cross-cutting.—Recent developments in the McAfee & Luttke lease on the Casa Grande property east of Big Pine, have resulted in arrangements for more extensive development in the immediate future. In preparation for the work which is to be done during the winter, a large amount of supplies have already been shipped to the camp to avoid any delay during the winter months in case the bad weather should make it impractical to come out. About six tons of ore is already on the dump, sacked ready for shipment. This ore has been carefully sampled and assayed and averages well over $100 per ton.—The Goldfield lessees, Stevens & Horn, have taken a lease on the old Montezuma mine and expects to be starting regular shipments to the smelter at Keeler before the end of the year. The Montezuma, which has yielded some of the richest silver ore in the district, is in the foothills of the White mountains a few miles distant from Big Pine.

MARIPOSA COUNTY.

The Kolbak mine on Saxon creek is getting ready for business. A hunting mill and lumber have been pur chased and the company expects to be in working order at an early date.—The Moonlight mine, on the North Fork of the Merced river, owned by R. B. Stolter and Dan Wagner, was sold last week to Samuel Harris, who is working a group of mines adjoining the Moonlight. The sum paid has not been made public.—More stamps are needed at the Mariposa mine, as the present number is insufficient to work the amount of ore being taken out by the several leases. Manager Moore says he will add five or ten more stamps as soon as possible.

PLACER COUNTY.

Six men are doing work at the Big Gun at Michigan bluff, preparatory to working the mine this winter. This is one of the famous hydraulic mines of the county. It formerly belonged to the Van Emans, but the largest part is now owned by Alfred Dixon. It is reported that he has made a deal with W. S. Fletcher, who intends to work it this winter.—The slope at the old Whitegold claim at Last Chance has been sunk 80 ft. in the expectation of striking the old shaft channel. A surprise awaited the company, as instead of the shaft, a new channel was opened up. There is but little washed gravel in the new channel, but it carries heavy fine gold. Twenty men are employed.—The mill at the Peckham hill has been finished, the boiler installed, and the adit nearly cleaned out preparatory to regular work.

SHASTA COUNTY.

The breaking of a new cable in the incline shaft at the Basalina mine was the cause of the death of an Italian miner. The cable showed no flaws and the cause of the break is inexplicable.—E. J. McHugh has finished the
assessing work on the Michigan and McClure groups of copper claims, the work being done by the creditors of the Phoenix Securities Co.—The oil excitement in Anderson has subsided, as a big flow of water was struck at Shade farm at a depth of 300 ft. and operations ceased. The well-drilling outfit is now working on the big well of the Anderson Water Company.

SIEGEL COUNTY.

Alex Deible and A. C. Widler are doing the assessment work on the Australia lode claim, in Sing canyon, one mile south of Downville. The claim is owned by Richard Pfein.—Frank P. Roddy is doing the assessment work on the Lust Resort claim on the hill back of Hansen’s ranch.

SISKIYOU COUNTY.

R. A. Murray and his associates expect to operate the Finley placer mine at Sawyers Bar during the winter and are now engaged in preliminary arrangements.—A company of Chicago men has purchased the group of quartz claims on Taylor creek belonging to Harris Bros., for $70,000. Taylor creek is a tributary of Salmon river. The new owners will begin operations at once.—Dane Spear and others are doing assessment work on the King Solomon group of mines for the Canyon Mountain Mining Co.—W. A. Cooper, of Eureka, has re-leased the Coburn hy- draulic claims on Ceci creek, near Yreka, and intends to start work as soon as season opens. The second Happy Camp placer property was sold at sheriff’s sale recently.

The Happy Camp is one of the most valuable properties in the county, consisting of several hundred acres of ground, mostly patented, as well as valuable water rights and mining machinery. It was owned by the Oregon Gold Mining & Water Power Co., which spent about $200,000 in development and equipment. It had not been worked for several years. Reeves Davis, of San Francisco, was the purchaser, the price being $10,500.

TRINITY COUNTY.

Paul Gein was washed down the full length of the 2500-ft. LaGrange fire one day last week and not only lives, but escaped without a broken bone. He was at work re- pairing the flume when the water was turned in unex- pectedly and he was carried along with the boulders and gravel by the mighty flume of 6000 inches and shot over the rock pile at the end of the sluice. His escape from drowning is no less marvelous than the fact that he was not crushed to death.

TUOLUMNE COUNTY.

Arrangements have been perfected to begin extensive operations at the Black Oak as soon as water is furnished for the mill. Seventy men will be employed.—The stamps in the mill at the Mack, at Big Oak Flat, began crushing a good quality of ore last week.—Want of fuel has forced a suspension of operations at the Wild Cat.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Argentine Exploration Co. has been organized with a capitalization of $1,000,000, shares having a par value of $1 each. Development has been put under way upon the Morning Star lodes No. 1, 2, 3, and 4, situated in West Argentine, near the base of graveys and Torrey’s peaks. In resuming an adit 40 ft. a vein was intersected, a streak of ore being exposed that is 18 in. wide and carries $47 per ton in silver and lead. A plant of machinery will be installed in the early spring.

B. J. Martelon has been appointed manager.—The Reo M. Co. has filed articles of incorporation with a capital stock of $250,000, shares having a par value of $1 each. Work has been started in the development of the Martelon and Mitchell lode claims, as Cherokee gulch between Sherman and Republican Mtn. An adit has been run 400 ft., but it will be necessary to drive 125 ft. before the Martelon vein will be reached. Thomas Cudahy has been named as manager.—It will be a campaign of development to be started at the holdings of the Georgetown M. P. & T. T. Co., on Columbia Mtn. A contract has been made with the Siga-
MINING and SCIENTIFIC PRESS  

DECEMBER 12, 1908.

CARRIES SILVER AND COPPER.—The Danville M. & M. Co., under the management of Martin Housh, is making excellent headway on its operations at the Reuben. One carload of high-grade ore has already been shipped and another will be ready soon. The management is not planning to make any more shipments this fall, but will go ahead with development throughout the winter and will have a large amount of shipping ore on hand when the trains are open in the spring. The property is being worked through the Trinity tunnel, the property of the Trinity Mining Company.

LAKE COUNTY.

Arrangements are being made to install a plant of machinery on the Gallagher property on Yankee hill, which was recently taken under lease by a number of local mining men. A boiler is now being installed. —William Harvey and associates, who are working the Result property, have recently opened a good body of iron ore, from which they expect to start shipping in a short time. The best of it runs about five ounces silver and a heavy excess in iron.

—Arrangements have been made to increase the output and also the force of men on the Hilltop property in the Horseshoe district, which is now being operated by W. F. B. Berger. The Colorado & Southern switch which connects with the Hilltop from Leavick is being improved, preparatory to handling the increased tonnage. As soon as the necessary preliminaries are complied with, the Hilltop will be shipping about 260 tons per day, the output consisting chiefly of a low-grade zinc ore, most of which goes to the smelters in Kansas. —S. P. Peetan received the machinery last week for the B. P. Mining Co.'s shaft on the Bufalo President property on Rock hill. He is busily at work getting it in place and hopes to have everything connected up and ready for sinking by the first of the year. Electrical power will be used exclusively and the line is already in place.

OURAY COUNTY.

The foundations for the 10-stamp mill being built by the Torpedo-Eclipse are completed and part of the frame-work is up. Andrew Wallace, of Montrose, is in charge of the erection. —Work was started this week on the Calliope north of Ouray under the direction of Tim Manion, who will have charge of the operations to be undertaken. It is controlled by the Calliope Tunnel & Mines Co., which was organized about a year ago. The company is financed by Eastern parties, and is reported to have sufficient means at its disposal to drive the adit to its completion. At present a force of about 25 men will be at work.

SUMMIT COUNTY.

The American Zinc Extration Co., of Leadville, has completed the overhauling of the Little Sallie Barker property, and is now planning to operate it extensively. The mine is a heavy zinc producer, and the product will be shipped to the plant of the company at Leadville.—The Colorado & Southern reports a heavier tonnage from the Kokomo district during the past month than they have hauled out of that place during the same length of time in several years. A number of large mines there are getting on the shipping list.

TELLER COUNTY.

The shaft on the Laura Lee claim on Mineral hill has been unraveled and sinking has been resumed. The shaft, now 130 ft. deep, is to be carried down to the 250-ft. level before any further lateral work is attempted and the equipment, now consisting of a horse-whim, is shortly to be replaced by a modern mine plant. George F. Brittain, who holds a lease and bond on the property, has interested Eastern capital in the venture and a mining company, to be incorporated under the name of the New Pearl Gold Mining Co., is in course of organization. —A two years' lease, expiring January 1, 1916, has been secured by James M. Wright, president and general manager of the Joe Dandy Mines Co., on the main shaft and workings of the Eclipse mine and territory adjacent thereto on Battle and Squaw Mtn., owned by the Keener Gold Mining Co.—Joseph Brentlinger and associates holding the lease on the main shaft and workings on the Old Gold Mines Co.'s property on the western side of Beacon hill will install an electrically driven compressor and operate on a larger scale with the use of hammer drills. A promising orebody has been exposed west of the shaft at the 250-ft. level and the lease is already on a paying basis.—Philip Argall, of Denver, consulting engineer of Stratton's Independence Limited and the designer and manager of the new cyanide mill of that corporation, is authority for the statement that the new plant will be the largest in the district. The Postcock mine has been financed and, it is reported, will soon commence the erection of a tramway to carry its ore to the railway. The mine was formerly a shipper, but has been closed for a year or more.—The United Placers Co., which is now about to secure patents to 1100 acres of ground, is planning an extensive flume and power line, work on which will begin this winter. The flume will be eight miles long. A power transmission line will be run from the mill to the mine. The work will be pushed all next summer and it is hoped to be mining by November.—The Idlewild Mining Co., which owns a group of five claims near Elk City, has purchased supplies for immediate shipment to the mine, and will start winter development at once. A 400-ft. adit is being driven to tap the ore at the intersection of two veins and at a depth of 250 ft. Over 60 ft. of the work is now completed. When the shaft is reached drifters will be run in four directions to explore each vein.—The Crackerjack mine is being worked by lessees, who are now employing 15 men. The stamp-mill is shut down until enough ore is on the dump to keep it running for several months. Supplies are being sent in for the winter. —A four days' run of the five-stamp mill on the Espey property at Newnome has given a gross clean-up of $5400. Supplies and some repairs have been purchased and sent in. The mill will at once resume and will run for a portion of the winter at least.

Elk City, November 27.

SHOESON COUNTY.

(Special Correspondence.)—The affairs of the Amador Copper & Gold M. & M. Co. still continue to occupy the limelight of the mining industry of the Coeur d'Alene. A visit made to the mine during the week by three of the leading officers of the Company, as it is at present organized, and a lengthy report made of the showing in every level. A copy of this report has been issued to the stockholders of the company, with an offer of their expenses, that they will be glad to pay all expenses of a visit to the mine of any doubting stockholders, provided that if the report be true the visitors will pay their own expenses. In addition to this a meeting of the Western stockholders was called in Wallace last Monday and attended by D. E. Mackinnon, as well as many holders from all over the country. The meeting was called more for the purpose of discussing ways and means than anything else, and at the same time to offset the effect of the meeting of Eastern stockholders held in Chicago. After debates lasting several hours, in which the general tone with regard to the future of the property was optimistic, a set of resolutions to the following effect was adopted: The stockholders of the meeting desire to place themselves squarely on record as favorable to the continued management of the property by D. E. Mackinnon, "believing that the success of this
enterprise and our investment is best safeguarded by the man who has never broken a promise to us and who has built up a great enterprise with consummate skill and bulldog tenacity." The stockholders condemned in the severest terms the management of the Amador mine since May 1, 1907, at which time Mr. Mackenzie retired as manager and was succeeded by a management controlled by George Lill and others and since which time the property has been at a standstill. The stockholders conclude by pledging themselves to support all action taken by the present directorate in anything that may forward the interests of the mine. A rich strike of copper ore has been made in the Ruby group of claims southwesterly from Lookout and about four miles from the Chicago, Milwaukee & St. Paul railroad. The strike was made by Patrick Sullivan and Adam O'Donnell, who uncovered the vein and found it to be a true fissure eight feet wide. At a depth of only 25 ft. an orebody was opened, the lowest assay of which gave returns of $101 gold and 51% copper. Some assays are as high as $121. It is the intention of the owners to work the property as a private corporation and it is believed that shipments of ore will more than meet the expense of development.—Joe Clark, foreman of the Shoshone Concentrating Co.'s mill, at Sweeney, has resigned and will go to take charge of the old Perlew property near Victor.—A contract for 100 ft. of shaft-work at the Bullion property has been let to Larry Ryson. This will take the shaft down to a depth of 300 ft., and if the present indications of improvement continue, the property will be one of the best copper mines in the district.—At a meeting of the board of directors of the Hypotheek Mining Co. held in Wallace it was decided to patent the nine claims of the company and to install a hoist with a capacity of 1000 ft. to replace existing machinery.—A certificate of amendment to the articles of incorporation of the Paragon Mining company has been placed on record by which the name of the company is changed from the Paragon Mining & Manufacturing Co. to the Paragon Consolidated Mining Co. It is also stated that the affairs of the Company are to be entrusted to a board of trustees consisting of not less than seven and not more than nine members.—The machine drills, compressor, and all the other machinery recently purchased by the Liston Mining Co. have now been put in place at the property and work has commenced on the driving of the 2000 ft. adit. A contract for 500 ft. of work will be let about January 1.—A strike of good copper ore has just been made on the property of the Josephine Mining Co. on the Montana side of the State line. The ore was discovered near the drift from the bottom of a 50-ft. shaft and consists of two feet of clean shipping ore carrying solid chunks of bornite and a large quantity of milling ore. Assays show 14.5% copper, 23.9% lead, 4.2 oz. silver, and $3 gold. A hoisting plant will be installed at once. The property is under bond to Dan McInnis, James McGinnis, George Loop, Forest Frazer, Claus E. Anderson, and C. M. Weller, all of Wallace.—Wallace, December 5.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—With the recent rise in the price of zinc ore a number of plants which have been closed down are planning to resume operations throughout the Missouri-Kansas district. The Isabel and Comet mines at Alba, which have been idle for some time, are beginning to operate again. The Comet is a comparatively new producer, beginning work several months ago, but has stored its ore waiting for higher prices. Its product is said to be among the richest ever taken from the mines in the Alba camp. The Zephyr Property, directly north of Alba, is active again. This has been among the best producing tracts in that part of the camp. The 125-ton plant of the Wilson Mining Co., in Spring City, is to be started again after several months' shut-down. The old workings have been abandoned and a new shaft sunk 300 ft. from the mill. A tramway has been built from the shaft to the mill and machinery will be installed for the new work, while the finer will be hauled down the tramway to the mill. Two drill-holes show ore, one 5 ft. of galena and the other 11 ft. of zinc blende.—The old Kathleen property in Belville is to be re-opened after a shut-down of several years. The drifts are very small, blindly following the ore trend as it was developed before the general use of heavy timbering. There is still a large amount of ore underlying the lease, as five draws centre there, all rich in ore. It will be operated as soon as drained.—Besides the re-opening of idle leases many companies are extending their developments on leases already active. The Mohler-Smith Co., at Carl Junction, has begun the development of an additional lease. This Company has thoroughly developed several hard leases in this camp and reclaimed a camp in which several disastrous fires have occurred. It is now planned to use a steam-shovel when work is begun in new ground. The new work will double the production. A sub-lessee has recently opened a 20-ft. face of ore which runs 30% zinc-blende.—The Merry Widow Co. has completed the ninth hole on its lease in the Midway camp and has found ore in five holes above the 50-ft. level, and a shaft will be started at once. The Merry Widow is in the vicinity of the Osyka, the Kallan, and the Florence, which have done extensive development work during the past six months.—Jesse Paul and associates, operating a sub-lease upon the Florence tract, have made a rich strike of shallow ore, at 14 ft., and during sinking a large quantity was taken out,—The sheet-ground area west of Joplin is being developed. Two companies have made rich strikes recently. H. E. Farwell has completed two drill-holes in the district, and found ore 25 ft. thick were penetrated. A large amount of development is planned during the coming year. This sheet-ground tract is comparatively new, having been developed during the past year, and is as rich as the famous north Webb City tract. Its development will mean much to the Joplin camp.—The North Kimmerly Mining Co. entered the producers list for the first time last week. The shaft has just been completed and five drifts run, all of which are 200-ft. mill is on the ground. The ground is soft and requires heavy timbering.—The Maple Leaf L. & Z. Co. is sinking a new shaft in the Daungow district on a lease adjoining the Wolfsear Co. The shaft is down 40 ft. Several new milling plants are under con-
rection and will be completed shortly. The Coahulla Co. at Deenweg is building a 500-ton plant which will soon be producing. The Montana Co. is building a 200-ton mill upon a lease at Smelter Hill. A 100-ton mill already on the lease is to be removed; only a small portion of the machinery will be used in the new mill. Jones, Wetmore & Hart are completing a 200-ton mill upon a lease of the American Z., L. & S. Co. at Orogozo. The lease is in the old bed of Center creek and during high water the whole vicinity is covered with water. The mill and exchanges are being driven foundations to prevent overflow. A mill will be built in the Spring City camp by Arthur Scott & Co. A shaft is in ore at 95 ft., although the drill entered ore at 110 ft. The formation is such that the ore cannot be easily cleaned on hand-jigs and a mill will be constructed. A former company abandoned the ground after sinking within a few feet of ore. The Maude L. mill is to be moved from its present site, in the Chittwood camp, to a lease farther north. Both are owned by Harry Gunning. The work will be completed in 60 days.

NEVADA.

ESMERALDA COUNTY.

An increased flow of water was encountered a few days ago in the shaft on the Clermont, which is being sunk by the Goldfield Consolidated Mines Co. Another pump has been installed. This shaft is nearing the 300-ft. mark and is now one of the deepest holes in the camp. A streak of ore, ranging in width from a few inches to two and a half feet, assaying as high as $100 per ton, has been struck on the Ricker lease on the Velvet property, which is part of the holdings of the Goldfield Merger Mines Co. A strike of pay-ore was made last week on the Sure Thing claim of the Brown Bonanza group, 10 miles south of Goldfield. The find was made while doing assessment work. The owners are so encouraged that they intend to develop the property extensively. It is said that the management of the Big 4 lease at Rawhide will erect a small mill.

HUMBOLDT COUNTY.

Summerfield & Pearce's teams are hauling in a carload of 15 tons of high-grade ore from the Kennedy and Benton mines, at Kennedy. As soon as it has all been brought in, the ore will be shipped to the Selby smelter, and it is expected that the shipment will net fully $100 per ton.

W. J. Smith and associates, of San Francisco, have purchased the property of the Gold Prize Mining Co. in the Seven Troughs district. An adit will be started at once and later on machinery will be purchased and a shaft sunk.

LINCOLN COUNTY.

George P. Spittal announces that the Nevada Victor Co. will erect a 10-stamp mill on its property in the Crescent district. The machinery has been purchased and is expected to arrive within 30 days. The plant will treat the ore from the Black Rock and the Hillside mines and will also do custom work.

LYON COUNTY.

The Utah-Yerington Mining Co. has settled the litigation which has been going on for the past two years, and has acquired the equity of the Home Bee in all property in litigation. The settlement was on a stock basis, the amount given not being made public. The settlement was brought about through the efforts of A. G. Guthel, who has been at work on the matter for some time.

NYE COUNTY.

A number of Eastern people have secured the Canyon mill at Manhattan and have made a substantial payment on the property. The Thanksgiving company is preparing to have 1000 tons of ore run through the mill. A small portion has already been treated and the returns are more than satisfactory.

G. S. Johnson and S. C. Burr are authority for the statement that the Round Mountain Central Mining Co. will begin operations at once. It is proposed to sink a shaft near the Fairview and Daisy line and a half and head-frame have been purchased.

California Power Co. has completed three of its power units, aggregating 10,000 kw., or practically 23,000 hp. of material to extend the capacity of the Round Mountain and Round Mountain has been purchased and work on the surveys is now under way. The line from Millers to the sub-station, which will be built at Central, two miles west of Manhattan, will carry the full capacity of the generating plant at Bishop. The voltage on this line to the sub-station will be 69,000, where it will be reduced to 2200 volts for transmission to Manhattan and Round Mountain. It is expected that the line will be available at these places by April 1.

Work on the Big Ten group, 18 miles southeast of Manhattan has closed down for the winter. George LeDuke, who is manager, reports having opened up a 12-ft. vein of milling ore on the Big Ten No. 1, besides three other smaller veins. A Chicago company, under the management of Judge Melvin, which has been developing a group of claims near the Big Ten, has also closed down for the winter. The total output of the Tonopah mines, for the week ending December 5, was $411 tons, of an estimated value of $135,275.

CANADA.

BRITISH COLUMBIA.

The Keremeos Copper Co., owned by Spokane men, has let a contract of 100 ft. of adit to be driven on one of its three claims, near Keremeos, in the Similkameen. The Company, which is headed by Dan Schultz as president, has been developing the claims for several years, and now has 1500 ft. of underground work done. A 500-ft. adit is to be driven to tap several known veins on the Bell Mining Co.'s properties on the Wallace Mtn. The veins carry ore in paying quantities on the surface, and the intention is to tap the leads at a depth of 200 ft.

YUKON TERRITORY.

All Gold creek is among the creeks being worked this winter. The stream has received more or less attention since '85, and a large number of men have been there at various times. All working out the river at present are working on All Gold this winter at the mouth of Lucky. McConachy and partners have been working All Gold hillsides for several seasons, and have a hydraulic proposition of much promise. It is said that they can get as much as 40c. per square foot of bedrock. They have 10 acres of ground. Dave Ennis, on No. 6 Gold Run, kept working and washing gravel on the top of the ground this year. October was his peak. This is his first working and he plans to wash. Nels Boyd and Jepperson, owners of S2 Below on Sulphur, are planning to install their new steel conveyor there in March, and then to start working and washing the gravels underground by hydraulic process.

The ground on S2 is 25 ft. deep, and there is four feet of gravel. The new method is to hydraulic out the gravel, conduct it through sluice boxes underground, and convey the tailing to the surface. Several men required in the past to shovel in will be eliminated.
The four drills on the Boyle concession, owned by the Canadian Klondike Mining Co., which operates what is known as the Bear Creek dredge, have been shut down for the past season. The company has not announced its intention of hiring in any more dredges immediately, but has kept plugging away over the concession the last season with the four keystones. This style of drill has been used successfully on the concession for years, and the drills have been a great factor in finding the paystreak ahead of the dredge, thus avoiding the working of worthless ground.

Forty-five men are engaged putting the Bear Creek dredge into condition for work next spring. The hull is being strengthened and given a general overhauling. The dredge lies in a slough at the edge of the Klondike about a mile below the mouth of Bear, to which place it has followed the pay streak in general work the last three seasons. The dredge started work the middle of August 1905 and has worked continuously through every season since, accomplishing this year the phenomenal record of running until November 9, and then having to shut down only because of the exhaustion of the fuel supply.

Caucaus Copper.—Magnetic Concentration.—Definition of Mineral.

—Copper in Siberia.

The Caucaus Copper Co. is an enterprise that was started eight years ago for the purpose of developing some extensive copper properties in the south of Russia close to the boundary of Asia Minor. The enterprise was taken up by a number of influential London merchants conjointly with the London representatives of J. P. Morgan & Co. There is no doubt that the copper deposits are extensive, but the trouble is that they are low-grade, silicious, and friable, so that concentration has proved difficult. At one time raw smelting was tried, with disastrous results, owing to the immense amount of charge that had to be passed through the furnaces. Many experiments were also made with water concentration, but unsuccessfully. Afterward Knox & Allen, of New York, were asked to advise on the subject and they decided to try the Wetherill system of magnetic concentration. The plant had been completed and was in working order early this year, when unfortunately the power-house was burnt to the ground. After a delay caused by re-building, the plant was once more started in October and before long we should have some news as to the results. During the summer a new wet concentrating plant to treat 150 tons per day has been erected, so that at the present time the old plant and new are working side by side. The directors, among whom there is now Mr. Colquhoun, lately manager for the Arizona Copper Co., are well aware they still have a difficult task before them and are not making any rash promises. Large sums of money have been spent by the company. About £400,000 in shares and cash went as purchase price and over £750,000 in cash has been spent in development and machinery.

In your issue of November 19 I gave some belated details relating to a dispute between the Great Western railway and the Caucaus China Clay Co. relating to the ownership of mineral rights under the land over which the railway runs, and I mentioned that the whole gist of the matter was the definition of the word ‘mineral’. The case has since gone to the Court of Appeal, where it was re-argued at equal length. The arguments were amplified and the points of view varied, but eventually the appeal was dismissed and the judgment of the court below upheld. Your readers will remember that the Great Western Railway brought an action against the Caucaus company to prevent them from winning the clay from ground adjoining or under neath the railway. The Caucaus company owned the mineral rights under the railway and claimed that they were therefore entitled to mine the deposit. The railway company argued that china clay was not a mineral, an argument that introduced endless confusion among the scientific witnesses. The judge eventually held that china clay was a ‘mineral’ within the meaning of the act and gave judgment for the Caucaus company. In the Court of Appeal the same ground was gone over again, and the railway company laid great stress on a judgment given under the same act in another clay lawsuit. In this other case the clay was quite a different substance, being a recent deposit and forming part of the soil. Certain parties wanted it for use in making bricks and claimed it accordingly as a mineral, but were unable to substantiate their claim in the courts, which held that the clay was part of the soil and not a mineral within the meaning of the act. The judges trying the appeal in the Caucaus case pointed out that these two cases were entirely different and had no bearing on each other. Consequently, they upheld the contention that china clay is a ‘mineral’ within the meaning of the act. In all probability the case will now go to the House of Lords to be argued once more.

The Abasbar copper properties have recently been introduced in London by the group that has the Spassky mine in hand. These mines are in the Akmolinsk province of Siberia, and the Spassky is well known as an unusually rich deposit. The properties of the Abasbar company are situated a few hundred miles farther to the west and are equally noteworthy. They are situated 230 miles northeast of Penowsk, which is an important centre on the Orenburg - Tashkend railway. The formation is unusual. The country is flat, but contains a plateau 70 ft. above the level of the rest of the district. This plateau occupies about 20 square miles and consists of a sandstone deposit. At various points there are malachite outcrops and at depths of 50 to 70 ft. from the surface are found flat beds of bornite averaging 3 ft. thick and containing 15 to 20% copper. Prospecting by shafts, drifts, and diamond-drills proves the continuity of the deposit over considerable areas. Pelley, Harvey & Fell, the consulting engineers, are careful appraisers. They state that over one small portion where the prospecting has been specially concentrated the existence of over 200,000 tons averaging 14% is a practical certainty, while over other parts where preliminary investigations have been made the possible ore may be put down at seventy million tons. The ore deposit is therefore interesting and important.

TORONTO, CANADA.

Break in Cobalt Stocks.—Restrain of Wild-Catting.—Consolizations of Cobalt Mines.—Electric Iron Smelting.

The market for Cobalt mining stock broke badly this week with a general drop in prices all along the line. Where there had been heavy buying in anticipation of an American demand after the election, which failed to materialize to the extent anticipated, and some speculators in futures were unable to fill their contracts or were obliged to realize at a loss. Another cause of the reaction in listed stocks is the bewildering number of new formations and the diversion into these channels of capital that would otherwise have been put into the older established issues. Undeterred by the experience of the former Cobalt boom, and the dropping from the list of numerous speculative enterprises formerly quoted at high figures, which have failed to make good, a large amount of money has during the last few weeks been risked on temptingly advertised prospects, offering shares at bargain-counter rates. Some of these may turn out all right eventually, but in the meantime the effect has been injurious to the market for dividend-payers, and is calculated to bring Cobalt securities generally into disrepute.

The Toronto branch of the Canadian Mining Association has for some time been urging the Provincial Government to take such steps for the suppression of ‘wild-catting’ as are authorized by the provincial laws. There is no legislation whereby speculators can be prevented from taking chances in prospects, even of the most dubious character, but in one direction the law is strict, namely, in demanding that all prospectuses and advertisements shall give full and explicit information concerning the details of a flotation, on which a prudent investor would wish to be informed. But so far this has never been enforced, nor its violation punished. Last week, however, Provincial Secretary Hanna published an announcement to the effect that
much richer ore than was obtained from the same vein at 80 ft. The Crown Reserve recently paid the Provincial Government $10,257 as royalty on the output for three months.

S. Bennett, a trusted employee of the O'Brien mine, who had access to large quantities of rich ore, was convicted on November 17 of stealing 320 lb. of ore, nearly all silver nuggets, and sent to jail for eight months. Other cases are pending.

Dr. Eugene Hasanel, Director of Mines for Canada, has gone to Sweden to be present at the starting of a new electric furnace erected by a firm of Swedish ironmasters at Dumafret. This furnace is claimed to be superior in design to any yet devised. As a result of the Sault Ste. Marie experiments in electric smelting, under Dr. Hasanel's supervision, the first experiments were made by experts engaged by the Swedish firm. The Dumafret furnace will use 300 hp., in place of the 250 used at Sault Ste. Marie, and a furnace on the same plan, it is stated, can be built at a cost of $20,400 to use 3000 hp. and produce 10,000 tons of pig iron per year. The cost of production per ton by the Swedish process is given as $12.03, which is three-fourths of the cost of production by ordinary methods. Dr. Hasanel will report on its applicability to Canadian conditions. The Mines Department is anxious to solve the problem of making electric smelting commercially successful, as only by this means can many of the large iron deposits of Ontario and Quebec, remote from coal mines, be rendered valuable. Even with an ample supply of fuel there are many of these deposits unsuitable for ordinary smelting, owing to their large percentage of sulphur, whereas the electric furnace can treat iron to a sulfur content as high as 21%. While in Europe Dr. Hasanel will also investigate recent improvements in producer-gas engines.

DURANGO, MEXICO.

Tamaulipas District. — Developments at Topia. — Los Animas Mine.— New Work at Mapimi.

Ferdinand Sustersick of Guadalupejara has acquired control of Los Reyes mine, in the Tamaulipas district, in the extreme western part of the State of Durango. He also has a bond and lease on another property in the same locality. The Los Reyes is considerably developed, showing good bodies of silver, lead, and gold ore. Mr. Sustersick is considering the advisability of erecting a smelting plant on the property, and if such improvements be decided on, the equipment will be hauled to the mine from Culiacan or some other place on the new line of the Southern Pacific, which is being built southerly through Sinaloa.

Tepehuaneas is on the west side of the National railroad, which extends north from Durango. It is the outfitting and shipping point for Guanacevi, Topia, and Portilla. Shipments from Guanacevi are now about 600 tons per month of crude ore and concentrate; bullion shipments amount to $50,000 per month, those of cyanide precipitate being about $18,000 per month. The bullion and precipitate shipments come from the Mexico Consolidated M. & S. Co., and the San Luis de los Reynas Co. The Tepehuaneas localities are La Aquia, San Roque, Santa Bárbara, and El Verde. Topia ordinarlly would ship 200 tons of ore per month, but there is only a small tonnage moving at present.

W. P. Miller of San Francisco has a long-term lease on the San José de Los Llanitos mines, situated in the Topia district, 90 miles west of Tepehuaneas. The group comprises five different properties, close together, which are well developed by levels driven in from the surface. The ore contains about 55% silver, 10 zinc, 20 with sulphides of iron, 5% copper, and lead, carrying 60 to 90 oz. silver and $2 gold per ton. The 10-stamp mill on the property was formerly equipped for pan-amalgamation and lixiviation, but the plant is being so changed as to provide for giving the pulp a chloridizing roast, this to be followed by cyanidation. Tests have been made by which Mr. Miller is assured an extraction of 85%. Heretofore some of the highest-grade ore has been sold to Tepehuaneas, the nearest railroad station, but in the future it is proposed to treat all grades
at the mill. Canelas is the nearest town to the Topia district, being 15 miles south. Canelas is half way between Tepetahuas and Culiacan, and it is claimed that eventually the packing, hauling, and travel from Topia and Canelas will go to Culiacan. The other mines in the Topia district which are active are La Portilla, Cardenas, and San Ramon. Near Canelas are some of the old Spanish mines which are now idle.

The Los Animas Mining Co. is operating in the Puebla nueva district, 33 miles southwest from the city of Durango, in the Sierra Madre mountains. The company is controlled by E. A. Wiltse of New York and S. D. Bridge of Monterey. This mine has been worked several years, and is developed by adits opening a series of veins. The mines, which contain silver and gold in quartz, strike through andesite. The mill is now having its capacity increased to 50 tons per day. The equipment consists of stamps, concentrators, tube-mills, and cyaniding facilities. The ore contains some iron sulphide, carrying gold, the silver being mostly in the form of argentite. It assays about $15 to $18 per ton. Water-power is used part of the year, but it is supplemented by steam. F. L. Norris of Durango is the company's consulting engineer, with S. H. Parsons in direct charge of the work.

The Santa Cruz M. Co., controlled by J. S. Venable, J. R.

Palmilla Mine, Near Parral, Mexico.

Donoherty, and Bert Roby, is developing a property in Otcac district, 35 miles west of the town of Durango, the work being in charge of Harvey S. Lord.

Some promising mine development is in progress at Mapimi, other than at the Ojuela of the Peñoles company, several of the new properties having reached the producing stage. The Suerte, managed by Geo. Stinson of Mapimi, is a mile south of the Ojuela, on the opposite side of the lime-

stone buta whereon the Ojuela is situated. Operations at Suerte are not extensive, but sufficient has been done to show irregular bodies of silver-lead ore in the limestone, contiguous to a porphry dike. A small shipment of this ore netted the Suerte people $50 per ton. In one place the orebody is 50 ft. wide. The Alberto, belonging to the Coahuila Mining & Smelting Co., of Viesca, has been producing since last May, the proceeds in six months having reached $25,000. Some of the ore shipped assayed 689 oz. silver and 70% lead. The principal part of the gangue is lime. The silver occurs as sulphide and chloride and the lead as galena and carbonate. The Alberto has been opened to a depth of 289 ft. on an incline shaft. W. H. Williams, superintendent of the property, states that an aerial tramway will be built, 21/2 kilometres long, to carry the ore from the mine to a loading station at the wagon-road. There is a wagon haul of 16 kilometres to Mapimi. The American M. Co. is developing the Tevuro, which adjoins the Ojuela and San Juan grounds. This is in charge of E. F. Sheets, who has completed 1500 ft. of development, and who is prospecting both

laterally and vertically with diamond-drills. The Coronado, Begasia, Tomatsia, Abundancia, and others are likewise being developed. The Providencia de San Juan de La Luz mine, situated 50 miles north of the town of Guanajuato, at San Felipe, is adding 30 more stamp to the 10-stamp mill and installing a cyanide plant to treat the medium grade ore in the mine and on the dumps. Shipments of high-grade ore have been sent to one of the Monterrey smelters. The ore consists of rough silver and gold in quartz, in about the ratio of 1 kilo of silver to 2 grams gold. The value of the ore is variable. The property is controlled by Mexican capital, Señor Robles being the superintendent.

MEXICO.

Vogelsteins at Oaxaca.—New Mills.—Option on El Tigre, Sonora.—Mines Closing at Parral.—Activity in Other Districts.

For some weeks numerous rumors have been current to the effect that the Consolidated Metals Co., in which the Vogelsteins are largely interested, is negotiating with the Magdalena Smelting Co., or the Oaxaca Smelting & Refining Co., or both, with a view to obtaining control of one of these enterprises and entering actively into the smelting business, and thus keeping for itself the ores it has under contract, instead of turning them over to the Tetuitan and other smelters. It is doubtful if there is any foundation for these rumors. Although the Vogelsteins have for a number of years been seeking a favorable smelting proposition in Mexico, it is not probable that they would consider entering that business at Oaxaca, which is rather out of the way for the building of a large smelting industry. It is certainly to be hoped, however, that either one or the other of the above-mentioned plants may be able to raise the necessary capital with which to resume operations, for Oaxaca is sorely in need of a custom smelter, the nearest being that of the Tetuitan Copper Co., at Tetiutlan, Puebla, which is almost entirely equipped for copper. The general condition of mining throughout the State of Oaxaca seems to be improving, and a number of mills are in course of construction or in contemplation. Among these may be mentioned the Gnishesa mill, which is nearing completion; that for El Socorro, of 10 stamps and a cyanide annex: the Frida Mining & Milling Co., at Zimilcan, which has resumed operation and given orders for a mill; and the new mill of the San Josè de Gracia, in Sierra Juarez, which is now operating and receiving ore from four fine looking stopes in the mine. Work has also been resumed on the Dolores mine of Adolfo Funes, in the Ejutla district, and the Escandon mill, in the Perras district, is again in operation. It is stated that the Boston-Oaxaca Mining Co., under the management of W. S. Main, will shortly resume work on the Placer mine, in the Tlacolula district, and will continue the present working-shaft to a depth of 200 ft., and will then cross-cut to the vein.

It is understood that the option that was held by either Phelps-Dodge interests or the Consolidated Mines Selection Co., for $7,500,000 on El Tigre mine in Sonora, has expired, and unless a renewal has been given, the deal is off. The statement has been made that this property, controlled by Kansas City people, has about $15,000,000 worth of ore blocked out.

With a suddenness sufficient to cause a severe shock has come the practical closing down of a number of properties in the Parral district in the State of Chihuahua, leaving it more quiet than it has been before in many years. The drop in silver last fall put a number of properties in distress, though practically all continued at work, hoping for better prices, but gradually new work was curtailed, the
lower grades had to be cut out, and finally, when silver dropped below 80c. it was the 'last straw'. The entire cutting off last month of shipments from the San Francisco gold was silence, but that, of course, is limited, and the prospects are not bright with the present falling silver market. The districts around the city of Chihuahua, continue the regular shipments of high-grade concentrate and bullion, as does also the district of Potosi. It is doubtful whether much sulphide can be produced at the rate of a little over one car each per week. This concentrate is produced on the Sutton-Steele dry-table concentrator. 

Estimates of Montana Metal Production.—Increased Ore Tonnage in 1908.—President Roosevelt and the Smelter Smoke Nuisance.

The State Mining Inspector estimates the value of the total metal product of Montana in 1908 at $57,945,000, of which he credits $45,195,000 to copper, $8,000,000 to gold, $2,259,000 to silver, and $2,500,000 to lead, an estimated decrease from the value of 1907 of about $2,000,000. The quantity of the output is materially larger, especially in copper and silver, but the prices have been much lower. Copper, for instance, will show an increase of nearly 29,000,000 pounds. At present the monthly output of copper is close to 30,000,000 lb., and the tonnage of ore is in excess of 15,000 tons daily. The number of men employed in and around the mines of the district is within about 15,000 of that number which marked the number at present employed being estimated at 10,800.

Reports from Washington are to the effect that the 'smoke nuisance' in connection with the operations of smelters has led to a recent conference with the President. It was rep- resented to him that the gases are destroying vegetation and forests and contaminating the streams so as to make the water unfit for irrigation or domestic use. President Roosevelt, it is said, decided to hear the side of the copper men before taking action. Several years ago a number of farmers residing in the valley adjacent to the Washoe smel- ter combined and brought injunction proceedings against the Washoe smelter, in an effort to close it. The case has been pending in the Federal Court of Montana for several years and has been a hard fought suit. Judge W. H. Hunt now has the matter under consideration and a decision is expected. In the view of this fact it looks not unlike a shrewd or questionable move on the part of the farmers and enemies of the Amalgamated Co. to make another direct appeal to the strenuous President to take a hand in the fight on the plea that the gases from the smelter were injur- ing the scrub timber and sage brush on the Government reserves in that part of the State. They did the same thing at the time they collected evidence to present at the trial against the smelter, and they succeeded in interesting the President in their case. Special agents of the three depart-

JOHANNESBURG, TRANSVAAL.

Labor Figures.—Passing of the Tailing Wheel.—Rand Profits Per Ton. —Mines Trials Committee.—Rescuing Narrow Reels.

For several months past, journalistic reports and the speeches of directors relating to the progress of Rand mining have been marked by a silence, as awakening as that coincident with the stoppage of a mill, upon all questions of unskilled labor. It is difficult to believe, however, that the old cry of shortage will not find expression once more in the near future. Even if there were still a superabun- dance of natives available for the active mines, one would be obliged to anticipate the abnormal demands to be set up by the many new properties, with doubts as to the means of their satisfaction. But already several companies are complaining of an inadequate supply; the difficulties attend- ant upon the employment of a considerable proportion of 'green hands' are normal. To some degree a moderate shortage is beneficial, and forces an economy of labor not always apparent in the rare times of surplusage, when companies almost instinctively absorb all 'boys' offered to them. The first indication of genuine scarcity appears when Kaffirs applying for work are taken regardless of previous records.

The number of natives now employed by the mining indus- tries of the Transvaal stands at a phenomenally high figure, and it is interesting to note the large proportion it constitutes of the total labor-force of the Colony. In all labor districts, the total number of native workers (including domestic servants) is roughly 243,000; of these 170,000, or 70%, are employed by 'mines and works'; and about 140,- 000 on gold mines alone. In addition to these Kaffirs, there are still 14,000 Chaminas, whose places must be filled before the end of 1909. The requirements of the industry may be placed at about 15 boys per stamp.

A great deal has been written of late, in the Mining and Scientific Press as elsewhere, concerning the 'passing of the tailing-wheel'. We have also heard at times of the passing of the Cornish pump, and even the gravity stamp. Certainly, the day of the Cornish pump has departed with the term 'gradual death', and a stamp would be sooner and so invaluable a factor in the past, the time has surely come for its abandonment in favor of electrically driven plunger- pumps or possibly of centrifugals, for mine drainage. But the gravity stamp and the tailing wheel fall under a differ- ent category, and are uninfluenced by the change of mining conditions. Their only enemy is technical progress. The gravity stamp, so far from retreating in the face of the outri- dings made upon it, and in spite of the auxiliaries sent to its assistance in the shape of tube-mills, has in many
respects increased in importance and security of tenure. What is to be the fate of the tailing-wheel? That pumps are now highly popular and are being widely installed to perform the work of tailing elevation from below the amalgamating plates to the spitzkasten serving tube-mills and cyanide works is unquestionable; so general, indeed, is this shifting of favor, that it requires little courage to predict the complete victory for the pump in all new fields of construction. It is possible, however, that this indicates but a transition stage. In the opinion of one leading metallurgist—whose full views cannot yet be published—there is the possibility of great economy in pulp-elevation by effecting it in two stages. Under recent conditions, the entire mill-pulp has been raised (perhaps 40 to 50 ft.) to the point necessary for the service of the sand and slime plant. A portion of this pulp, however, is eliminated by the classifiers for feeding the tube-mills and these machines are so placed—generally below the level of the main amalgamating plates—that a high lift is not required for their service. Consequently a great part of the pulp is needlessly elevated to the full height. By two-stage elevation, the total pulp will first be raised to a point enabling the tube-mill feed to be drawn off, and then the remainder, for the sand and slime plant, to be elevated to the upper classifiers. Under these conditions the tailing-wheel, the principal defect of which lies in its capital expense, may again be found advantageous; only in high lifts has the pump proved itself the better unit, for the cost of the tailing-wheel increases proportionately to the square of the radius. The truth of the oft-quoted statement that the Rand is a comparatively low-grade goldfield is constantly becoming more apparent in the light of recent returns. In accordance with universal experience, it is noticeably growing more dependent upon profits drawn from poorer reserves. Only by an appreciation of this fact can the true significance of increasing aggregate yields and profits be gained. An analysis of the Rand’s September profits (total, $1,025,000) provides striking evidence of the importance of ore yielding a return which in many fields would be quite unpayable. With average working costs of 17s. 6d. per ton, companies may be segregated as follows:

The yield of these 63 companies (representing the whole Rand) averaged $7.22 per ton, of which 62% is contributed by the amalgamating plates.

The Mines Trials Committee, recently formed for the purpose of encouraging inventors by investigating and putting to practical test promising ideas submitted to them, has already performed much work and has diligently waded through a mass of proposals purporting to raise the efficiency of metallurgical practice. Of course, there has been considerable heart-burning in many quarters over refusal of the Committee to spend money upon certain schemes, for the inventor is almost invariably past the influence outside discouragement, and, with him, lack of favor is merely a sure sign of ignorance or prejudice. However, the patents on the Rand have plenty of opportunities for the advancement of his ideas apart from the Mines Committee, which is only applied to by many as a last resource. The originator of new ideas in the States, on the other hand, perhaps in need of information as to the practicality of a scheme’s application to Rand conditions, should find the Committee of great service. The body represents every important mining group on the field—and represents them well. It may be repeated (circulars have already been widely distributed) that inventors are urged to provisionally protect their ideas before submitting them, to suggest what remuneration is required if adopted, and to give all possible information together with drawings and specifications. It must be borne in mind that the Committee only deals with devices or processes connected with ore treatment from shaft-head to dump, so that rock-drills, for example, do not fall within its field of activity. Several have expressed satisfaction with this limitation of scope, and perhaps the Committee will subsequently enlarge its field. In view of the approaching rock-drill competition, perhaps this particular appliance may still be specifically ‘barred’ with advantage.

Little has been heard recently of the ‘re-suing’ system of mining, because, presumably, it has been found so rarely applicable with success. Nevertheless the ‘jumpers’ continue to ‘re-sue’ some of their few remaining blocks of reef, and at the Windsor the system has been introduced with admitted benefit. Opinions are likely to differ radically upon the matter, and it must be confessed that it is frequently condemned or applauded upon somewhat flimsy testimony. Re-suing, briefly, is that system for mining narrow inclined reefs, of 3 or 4 in. width, by which the underlying waste is first broken out and packed in the stope, and the reef then blasted down (with as little waste as possible) and sent up for treatment. The object is to raise the grade of ore milled and avoid the expense of tramming, hoisting, and treating waste rock. Mining costs per ton milled naturally increase, but it is claimed by some that the increased grade more than balances the higher expenditure. In deciding the possible applicability of the system, it is necessary to consider whether the whole mill can be kept going on the re-sued ore, and also whether the greater percentage of surface sorting is practicable when working in the ordinary way. Under any circumstances, whether mined separately or in the single face, the waste can to some extent be stored underground. Probably the chief defect of the re-suing system is the loss of fine ore, which is commonly rather high in gold. The scheme was given an extended trial in the old Nigel mine, on the southern tip of the Rand basin, 80 miles southeast of Johannesburg. Re-suing was found costly in handling of explosives, and was abandoned completely in favor of ordinary single-face mining. The reef averages only 4 to 6 in. in width, and dips at 15° to 18°, lying on a slate foot-wall. This slate now makes a good floor to the stope. Pack-walls are still put in, but at a distance of about 40 to 50 ft. from the face, and are well made so as to catch a minimum of fine ore. The stopes are well braced down. The previously noted objection to re-suing is particularly well exemplified at the Nigel today, for it is being found profitable to pull down the old packs of slate and remake them, in order to recover the rich fine and the many lumps of ore inadvertently included.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The St. John Del Rey gold mine, in Brazil, is 4250 ft. deep vertically. The vein has a dip of 45 degrees.

‘Dig’ and ‘pug’ are the names given in the Australian States to that which the American miner calls ‘gouge’, and a Cornishman ‘hulk’ or ‘fluecan’, and which in the text-books is termed ‘selvage’.

The gold-bearing veins of Hog mountain, Tallapoosa county, Alabama, are in a granite core intrusive within slate. When the veins approach the slate they become poor, and at the contact they cease to exist.

Adjustment of a jig should be so made that the stroke will end approximately at the same moment as at which the particles in the ore fed attain their uniform velocity of fall. The reverse stroke should then be prompt, so as to quickly consolidate the bed.

The greatest altitude ever reached by man in a balloon ascension is 35,500 ft. Balloons for exploration of the upper air, fitted with automatic recording apparatus, have attained an elevation of 83,000 ft. (16.1 miles). The highest level ever reached by a kite is 21,100 feet.

The electric motor was first applied to traction operations on a commercial scale by Leo Daft in Baltimore, in 1885. Prior to that time successful demonstrations had been made at Saratoga and Coney Island by the Daft Electric Co., and as early as 1880 Edison had designed and operated an experimental electric locomotive with encouraging results.

Hanging valleys are characteristic of the scenery of southeastern Alaska. The wooded slope is threaded by a white cascade issuing from a big cirque or amphitheatre, the floor of which is 100 to 150 ft. above tide-water. In this elevated basin, held within rock walls, there is a lake, marking the former bed of a glacier. This is a ‘hanging valley’.

Vanners are used in the best mills, as yielding reliable all-round results in slime-concentration. The problems of slime-concentration have by no means been solved. This is still the weak end of ore-milling, and it offers an attractive field for the mechanical engineer. The modern form of vanner has an oscillating motion imparted to it, the simple side-shake being less effective.

Water is always present in volcanic rocks. No such thing as absolutely dry fusion of rocks occurs in nature. Hence there is an important difference between lavas and slags, and too close an analogy should not be drawn between them. Water lowers the fusion point of rocks, so that pastiness may result at temperatures which are by no means elevated. Water also facilitates crystallization of molten rocks.

The solidification of molten magmas is supposed to cause the extrusion of this magmatic water, which is undoubtedly an active agent in the formation of orebodies.

Old tailing offers no peculiar difficulty in cyaniding, except that ferrous compounds will be in excess, especially if much organic matter be present, and the consumption of KCN will be proportionately high. The effect of the organic matter itself is to increase the acidity, which in this case may often be removed by a simple water-wash. If not, recourse may be had to lime for neutralization.

Loess is strictly a name applied to a fine deposit in the lower Rhine valley, and in northern China. It differs from ordinary river-silt in its lower content of argillaceous material. Richthofen suggested that the Chinese loess had been carried to its present position by wind. The term is applied to exceedingly fine deposits of Pleistocene age found in Arkansas, where it is sufficiently aluminous to serve as an excellent brick-clay.

Electric furnaces of simple inexpensive design for retorting or melting are not available in the market, nor are they in general use. Perhaps the most successful electric melting furnace was one designed by J. Brom of Cologne and used for making glass. Becker and Völler have also produced successful furnaces of that type, controlled by a Brussels company, l’Industrie Verrieres el ses Derives. Gustav de Lavall, and Casorotti and Bertani have produced retort furnaces for zinc distillation, the patents of the latter belonging to the Società Elettro-metallurgica, of Lombardia, Italy.

Screening ores after dry-crushing cannot be successfully done in trommels, unless they be of very large diameter, and the speed be adjusted with accuracy to the burden: any variation in the quantity of ore fed will immediately result in poor screening. Regulation of the feed to any screen, whether wet or dry, is most important. Bumping screens are efficient for dry-screening, but are difficult to keep in repair. Tossing screens give excellent results, and are easy to make. The best device for dry-screening, however, is the gyratory screen, mounted on cone bearings, devised and generously given to the world many years ago by the late Eckley B. Coxe.

Open-hearth steel rails are now being used by some of the more progressive railroads, instead of bessemer steel. P. H. Dudley, of the New York Central R. R. Co., says that the phosphorus content of the new rails will be lower and probably the brittleness will be reduced, but the wearing quality has yet to be determined. The metal must be higher in carbon than is necessary in the bessemer process, with the use of 0.06% phosphorus. Unexpected results, however, follow seemingly trifling variations in composition, as, for example, rails rolled from basic open-hearth steel, in which the carbon was from 0.65 to 0.75%, were tough, but with carbon from 0.68 to 0.78%, much brittleness developed.
Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compli-ment. Insertion of any contribution is determined by its probable interest to the readers of this Journal.

Waters, Meteoric and Magmatic.

The Editor:

Sir—Under the above title there appeared in your journal a lucid article by T. A. Ricketts in which is brought out the fact that the water encountered in mines is usually confined to a nearly horizontal layer, below which the rocks are drier, as evidenced in the deep workings of many mines. I venture the following notes as a continuation of this discussion.

Recently there have appeared two large volumes, in each of which there is given a theory of the origin of ore deposits, with much detailed evidence, forming a scientific basis for the theory advanced in each case. One of these books is a "Treatise on Metamorphosis" by C. R. Van Hise, and the other is the "Geology and Gold Deposits of the Cripple Creek District" by Lindgren and Ransome.

The monograph by Van Hise gives his latest views and strongest evidence on his well known theory, which attributes most metallic ore deposits to the action of underground waters originally of a meteoric character. The paper by Lindgren and Ransome gives the best scientific basis, so it seems to me, that has yet appeared for the theory of the origin of ore deposits by magmatic waters, although the fact of the gradation between pegmatitic dikes and quartz veins or quartz dikes, as seen, for example, at Silver Peak, Nevada, is a very fetching argument, so strongly insisted on by J. E. Spurr.

The name of Van Hise is so intimately associated with the theory of ore deposits by meteoric waters that one is surprised to note in his monograph that he recognizes:

1. That crystallizing magmas give off water.
2. That this water is probably richer in metallic contents than any deep thermal meteoric water.
3. That such waters have produced ore deposits.
4. That there are complete gradations between purely igneous pegmatitic dikes and purely aqueous vein-material.

However, certain geological facts presented by Van Hise do not appear to have had adequate consideration. I refer to his 'zone of cementation' and its bearing on the underground circulation. It should be recalled that Van Hise recognizes two zones in the earth’s crust, a lower zone called the 'zone of flowage,' and an upper zone, called the 'zone of fracture'; and that he regards the circulation of meteoric waters as confined to this upper zone of fracture. This upper zone, moreover, he divides into two zones or belts, a lower 'zone of cementation' in which sulphide ore deposits are formed, and an upper or sur-

face zone of weathering in which the surface water acts as an oxidizing agent. His belt of cementation is so designated because in this zone when deeply buried, underground waters have deposited secondary silicea, etc., forming dense compact rocks from rocks originally porous.

Van Hise says, 'The strongest evidence of the vigorous and extensive character of the circulation in the belt of cementation is the fact that cementation is universal in it. Wherever porous rocks have remained long in the belt of cementation, an enormous amount of material has been deposited by underground aqueous solutions. . . . The great sandstone formations have been transformed to quartzite by deposition of interstitial silicea. In the San Juan district of Colorado, great tuff formations of Tertiary age have been completely cemented. . . . Wherever rocks are exposed which once possessed numerous and large openings . . . their general cementation gives conclusive evidence of a vigorous past circulation. In consequence of the process itself, the openings become smaller and smaller; consequently the circulation less and less vigorous, until when the process of cementation is complete, or nearly so, the circulation becomes very feeble. . . . In many mining districts, these conditions now exist. At the time of rapid deposition of the ores, there was a pervasive and vigorous circulation, which, as cementation continues, gradually became less and less, and finally practically ceased.' Van Hise would thus admit that a belt of vigorous circulation, such as he pictures elsewhere in his monograph as being nearly universal, is in fact quite limited as to depth where the rocks do not now contain capillary pores, and cites the Lake Superior copper mines as an instance. Now, if the underground water circulation is as universal as described, one would expect it to exist fully fledged in a region of precipitation like that of the Great Lakes. Moreover, Van Hise admits that in certain arid regions, like Arizona, the underground circulation may be feeble even when the rocks are porous, but he calls attention to the fact that the arid region of the western United States was quite humid in Tertiary and early Quaternary time, and the numerous fossil lakes of those periods, together with the character of the plant remains entombed in the lake sediments, conclusively prove this to have been the case.

Admitting that cementation was the work of meteoric waters, it is difficult to understand how the vast amount of interstitial filling that was effected by these waters could have been brought about by any but a vigorous circulation, and if we admit this we must also admit that these waters have cemented fractures, or in other words, formed vein deposits. It would thus appear that while a vigorous circulation of meteoric waters has existed in past times to a considerable depth in porous rocks, and that while this circulation may have been the cause of ore deposits, yet no such universal circulation does now exist in the crust of the earth as is pictured by Van Hise, nor did it ever exist in closely grained rocks,

Monograph XLVII, U. S. G. S., 1904.

and this would apparently include many igneous rocks, which enclose precious metal deposits.

However, nature is credited with being able to produce similar results in diverse ways. The waves on the scabore erode caves in the rocks against which they dash, and the winds of the desert do precisely the same thing in the rocky reefs against which they blow.

It would seem as if the argument of Van Hise, that cementation is a proof of a former vigorous circulation, has not been adequately met. Certainly the fact that the lower levels of mines are now comparatively dry does not disprove that a vigorous circulation may not have existed at the time the ore deposits were formed.

If, with Spurr, we consider quartz veins as dikes, being the silicaceous extreme of the differentiation of a magma, we must admit that there is a great difference between ordinary igneous dikes and aqueous dikes, in that the former produce but little chemical change in the rocks which they intrude, while the latter react strongly on the rock walls, taking into solution part of their contents, and depositing it elsewhere as vein material. Thus in the quicksilver deposits in the Lower Cretaceous limestones at Tértingua, Texas, the vein material of the lodes (excepting the secondary gypsum and the crushed and brecciated country rock) is calcite, which was plainly deposited by the same waters that deposited the cinnaabar. The reasonable conclusion is that the calcite was derived from the limestone at a lower level (the limestone is 1500 ft. thick), and not from a calcarceous magma in the barysphere. If these aqueous dikes take earthy material into solution from the rocks of the crust which they penetrate, why not also to some extent the metals?

The article on "Rock Pressure and Metamorphism" by H. M. Chance would tend to show that cementation takes place by welding, and the pressure to effect this is ascribed to thrusts. Mr. Chance thinks that cementation by welding will explain the formation of quartzites quite as well as the circulation of ground waters. In the case of welding, no addition of material would take place, but there would be a diminution of volume; while the formation of a quartzite by circulation of water carrying silice in solution would mean an addition of material but no great change in volume. If such thrusts as those described by Chance produce cementation, it is evident that cementation would vary in the same beds, for the strain would not be uniformly distributed, but cumulative.

Mr. Chance himself points this note, and states that it explains "the variations observed in sedimentaries, especially sandstone and grits, which in some places may be completely cemented, in fact almost completely converted into quartzites, while at other places near by they may retain the loose-grained porous structure of slightly cemented sand beds." While this is doubtless true, it is believed that this phenomenon is local and occasional, and bears little relation to the cementation of porous beds of enormous extent, and which show no such evidence of welding as is required by the stress or welding theory.

The best evidence on this question is to be obtained by an examination of thin sections of the rocks, and it should be stated here that Van Hise has studied many thousands of such sections in arriving at his conclusions. In effect, the thin sections of most quartzites do not show evidence of crushing or welding to a marked extent (at least this is true of massive beds covering large areas), but on the contrary, the original sand grains are often clearly recognizable, and the fact that the pores have been filled with interstitial silica is evident. In a thin section where pressure has been exerted on the rocks, we find in miniature what may be seen on a larger scale in the field, namely, fractures and faults, brecciation and granulation. We also find that the grains of quartz and feldspar which are under strain show undulatory distinction (that is, under crossed nioils), indicating that the originally homogeneous arrangement of the molecules has been disturbed by the strain.

Cyanidation of Silver Ores.

The Editor:

Sir—As a distant but appreciative spectator of the strenuous efforts now being made to develop the cyanide treatment of Mexican silver ores, I have read with much interest F. J. Hobson’s article upon certain phases of the subject, in the Mining and Scientific Press of August 1 and 8, and look forward to further elucidation of the points raised. The statements that argentite is readily soluble in cyanide solution, while practically no extraction can be obtained from native silver, are of great interest and importance, in view of the author’s long practical experience. It is not, however, clear how the interference with mill solutions of ferrous iron, existing as ferrous sulphate in the ore, is removed by preliminary treatment with lime, as the ferrous hydrate formed consumes oxygen, or reacts with potassium cyanide to form soluble potassium ferrocyanide. Also it is difficult to see why the percentage of moisture in a slime-residue is affected by the cyanide content being 0.01% KCy, or any other percentage.

Mr. Hobson’s equation to express the dissolving of argentite seems but a partial expression of the truth, and would be clearer if expressed in two stages, thus:

\[
\begin{align*}
\text{Ag}_2\text{S} + 4\text{KCy} & = 2\text{KAgCy}_2 + \text{K}_2\text{S} \\
\text{K}_2\text{S} + \text{KCy} + \text{O} + \text{OH}_2 & = 2\text{KOH} + \text{KCyS}
\end{align*}
\]

In the above form the origiu of soluble silver sulphide existing in limited quantity at any one time in the solution is explained, apart from the formation of this substance by the action of an alkali hydrate on base-metal sulphides present. Further, the above two-stage reaction is not incompatible with the formation in solution of soluble sulphur compounds other than sulphides or thiocyanates, as already detailed in your columns of May 2, 1908 (p. 594). Mr.

Hobson’s suggested reaction for the removal of soluble sulphides by means of potassium-zinc cyanide forms the basis of A. F. Cross’s process for regenerating free potassium cyanide from the double zinc-potassium cyanide in working solutions by means of alkaline sulphides. (Proc. Chem. Met. & Min. Soc. of S. A. p. 272, March, 1903, Vol. III.) This reaction is incomplete in cold dilute solutions, and it appears probable that soluble sulphides are likewise removed by oxidation during aeration of the charge, while the occurrence of sulphur in the zinc-boxes may also be attributed to reduction of potassium thiocyanate by nascent hydrogen, resulting in the formation of zinc sulphide, thus:

$$\text{KC}y + 2\text{II} + \text{ZnO}_2\text{I}_2 = \text{ZnS} + \text{KC}y + 2\text{O}_2\text{I}_2$$

As Bertram Hunt has already dealt with the hypothetical existence of mercurous sulphide and cyanide, and the incompatibility in solution of mercury compounds and soluble sulphides, I will confine myself to pointing out certain deductions from Mr. Hobson’s experiments which do not appear to confirm the conclusions at which he has arrived. For this purpose I have tabulated the results of the parallel tests as follows, though some details of their execution are lacking, as well as any mention of the original and final assay-values of the material experimented upon:

*The presence of lime in test (2) is inferred from the account of test (7).*

The relatively different extractions of silver and gold, under the varying conditions shown above, confirm the statement that the same factors affect differently the extraction from the two metals (see Mining and Scientific Press, p. 295, August 29, 1908).

As regards the silver, the use of free cyanide, together with potassium mercurous cyanide and potassium ferrocyanide, in (7) affords an extraction of 43%, intermediate between the plain cyanide results of 51% in (4) and 32% in (5), but the addition of lime to the reagents employed in (7) brings up the extraction to 85% in (3), so that the common practice of using lime is justified, while the advantages of potassium mercurous cyanide and its protective ferrocyanide in themselves are by no means clear. As regards the gold, plain 0.2% K_{2}Cy solution in (5) yields as high an extraction (90%) as does this same cyanide content, plus potassium mercurous cyanide and potassium ferrocyanide in (7), while all these reagents, together with lime, merely serve to reduce the efficiency to an extraction of 80% in (3), which might be a serious matter with silver-gold ores containing much of their value in the latter metal.

Mr. Hobson points out that aluminum interferences are neutralized by the addition of lime, presumably by precipitation of aluminic hydrate, but how this last insoluble precipitate passes out of the charge with the solution through the filter-cloth, and finally comes to rest in the zinc-boxes, is not clearly set forth. The rôle of reducer attributed to potassium ferrocyanide by Mr. Hobson seems hardly required in a solution which is assumed to be charged with soluble sulphides, and in any case the addition of a reducer seems undesirable when the dissolving of gold and silver is so greatly accelerated by the presence of available oxygen in any form.

In conclusion, Mr. Hobson inferentially supports by his equations the utility of oxygen as well as of lime in the dissolving of silver sulphide, but while mercury compounds in solution may assist by precipitating soluble sulphides, as when HgCl₂ was found to raise the silver extraction from 30% to 92%, the author’s ingenious theory, claiming still greater merit for the alleged potassium mercurous cyanide, would receive a more unqualified acceptance if supported by the publication of the results of a detailed examination of the properties of this substance, and its effect upon the cyanide treatment of silver ore.

Inefficient Metallurgical Treatment.
The Editor:
Sir—According to Mr. Hallet R. Robbins, A. B., B. Sc., London, in a recent article published in the Transactions of the A. I. M. E. (Birmingham meeting, October, 1908), inefficient metallurgical treatment is one of the main sources of loss with the Oriental Consolidated Mining Company.

Mr. Robbins made his observations during the latter part of 1905, while in the employ of this company as an apprentice in the Taraeel cyanide plant, and not during 1908, as this article would lead one to believe. From his lack of experience, and considering his short stay with this company, I venture to say that Mr. Robbins was not in a position to say whether or not the methods were inefficient.

This company is quite aware that its methods of treatment can be improved upon. Three years ago an experimental plant was erected with the idea of solving the metallurgical problem, and it is not too much to say that no other company has gone about the thing in a more thorough way than the Oriental Consolidated. In all probability, during the coming year numerous changes will be made in some of the plants—improvements in concentration and cyanidation; arrangements will also be made for re-concentrating, re-grinding, and further cyanide treatment of the old tailing dumps.

A. E. DRUDE.

Taraeel, Korea. November 2.

Ore cars of 150 tons capacity are being built for the Carnegie Steel Co., for use at its Pittsburg plant, and not for service between Pittsburg and Lake Erie, as reported by the daily press.

December 12, 1908. MINING AND SCIENTIFIC PRESS 807
ASSESSMENT WORK ON MINING CLAIMS.

Written for the MINING AND SCIENTIFIC PRESS
By Wm. E. Colby.

The performance of assessment work or annual labor on unpatented mining locations is a matter that assumes importance at this time of year. It is the purpose of this article to indicate briefly the nature of the annual labor required by our mining laws, and to discuss some of the questions that may arise in connection with such work.

Ancient Law.—From time immemorial the performance of assessment or representation work on a mining claim has been a condition controlling the retention of title. The Roman mining law, as shown by a recently discovered inscription, insisted upon continuous work. A cessation for ten days, or, in special cases, for six months, resulted in forfeiture of the mine. The old Germanic mining law was even more rigorous; continuous work, day and night, was a condition of the holding. This was later relaxed, until finally cessation from labor for a year and a day was allowed without confiscation of the mine. The amount of work required by statutory law in the tin mines of Cornwall and Devon varied. At one time a man retained his title for the first year by marking the ground; the second year by the improvements he placed on it; and the third year by the output of tin. Still earlier, the annual work required was the equivalent of one man's labor for three months.

Federal Statutes.—We see in the mining code now in force in the United States, points of strong resemblance to these ancient mining laws. Section 2324 of the Revised Statutes enacted in 1872 provided that "on each claim located . . . and until a patent has been issued therefor, not less than one hundred dollars worth of labor shall be performed or improvements made during each year . . . and upon a failure to comply with these conditions the claim or mine upon which such failure occurred shall be open to re-location in the same manner as if no location of the same had ever been made, provided that the original locators, their heirs, assigns, or legal representatives have not resumed work upon the claim after failure and before such location;" and Section 2 of the Act of 1880 (21 Stat. L. 61) amended the former section by providing, "That the period within which the work required to be done annually on all unpatented mineral claims shall commence on the first day of January succeeding the date of location of such claim . . . ."

Time of Performance.—It is evident that a locator has until December 31 of the year following the year in which he makes his location, to perform his annual labor. Whether he can perform the work during the year that he initiates his location and have it count for the year following is extremely doubtful. To be safe, the work should be done after January 1 of the year following the making of the location. While the statute is explicit on the point that the work must be done "during each year", yet the courts are loath to declare a forfeiture, and if a claimant commences his work before the end of the year, and prosecuted it vigorously, on working days during working hours, until it is completed, even though the greater part of it is done in the new year, his claim is not open to re-location. Under such circumstances, where January 1 falls on Sunday, and the claimant is in possession without working, but continues work Monday, an attempted re-location by a third party on Sunday is ineffectual. The same is true of an attempted re-location made before the usual hours of starting work. The postponement of work so as to run over into the new year is an unwise course to pursue, however, and the work should be completed by December 31.

Character of Labor Required.—In order to satisfy the statutory provision, the labor performed or improvements made must be of such character as actually to benefit and promote the development of the claim and facilitate the extraction of mineral therefrom. Sinking shafts, driving tunnels, making exploration cuts and excavations in furtherance of prospecting or mining operations constitute an unquestionable compliance with the statute. Roads and trails constructed for the benefit of a claim, and which are necessary in order to afford access to the mine in question, and buildings erected upon a claim for any purpose reasonably connected with mining operations and its development, may be counted as assessment work. The services of a watchman, where necessary for the protection and preservation of mining machinery and buildings, have been held to be sufficient, but not where there is no intention on the part of the owners to resume active operations within a reasonable time. These last mentioned expenditures, such as for roads, trails, buildings, and services of watchmen, are near the border line, and do not possess the unequivocal character of actual mine openings and excavations. However, the courts are inclined to be liberal in their interpretation of the statutory requirements, and any labor performed or improvements made in good faith that may, with any show of reason, tend to develop the claim, will be considered favorably.

Sampling or surveying a mine, unwatering it for purposes of examination merely, traveling expenses in reaching it, placing of tools, machinery, or buildings thereon, without any intention of using them permanently in actual mining operations, dumping tailing on a claim, have all been held insufficient and not within the spirit of the statute.

The Land Department has held that a quartz-mill situated on a claim and built for the benefit of that claim alone, is not an active agency in the actual development of the mine, since it has no connection with the operation of extracting mineral from the ground, but its function begins only when the process of mining has ceased. While the question involved was the sufficiency of improvements for patent purposes, the analogy would seem to govern in the matter of annual labor as well. This is an extreme refinement of the rule. If subjected to the same rigid test, many improvements that are now admittedly sufficient would be ruled out. The courts are inclined to look to substance rather than shadow, and where good faith on the part of the mine owner
is evident, they construe the law liberally and give him the benefit of any doubt. They are not inclined to be as technical in their rulings on the question of labor and improvements as is the Land Department in patent proceedings.

Group Work.—Oftentimes it would be a waste of labor to perform $100 worth of work on each one of a group of claims held in common. The natural and economic way to develop such a group of claims might probably be by means of a main adit or shaft, or, in the case of placers, by a flume, ditch, or reservoir, constructed for their common benefit. Under such circumstances it is permissible to perform all of the work, to the amount of $100 for each and every claim to be benefited thereby, on one or more claims of the group, or, in special cases, outside of the group. The work must be of such a character as actually to benefit each claim for which it was performed. For example, work on an adit, the portal of which is higher in elevation than some of the claims in the group, would not ordinarily benefit such lower claims. As a rule, the claims must be contiguous, and there must be some community of interest in all of the claims.

By special act passed in 1903, Congress provided that "The annual assessment labor upon [oil-placer mining] claims may be done upon any one of a group of claims lying contiguous and owned by the same person or corporation, not exceeding five claims in all. Provided, That said labor will tend to the development or to determine the oil-bearing character of such contiguous claims."

In the case of association placer-claims only $100 worth of labor is required on each claim, which can not, of course, exceed 160 acres in area.

Annual Labor, How Valued?—The statute is clear on the point that $100 worth of labor or improvements is required each year, commencing with the year following the location. A question sometimes arises as to what constitutes $100 worth of work. There are some district regulations and State statutes specifying the value of a day's work, but it is questionable whether these are valid. The value of a day's labor and of the material used naturally varies with the locality. The courts have held that the test is the reasonable value of the work or improvements, not what was paid for it nor what the contract price was. The actual value is the true test, though what was paid for the work is strongly persuasive as to value, and tends to establish the good faith of the claimant.

Proof of Annual Labor.—Many States have statutes requiring claimants to record affidavits to the effect that the annual labor has been performed, and setting forth the nature and value of the work. No serious consequence can result from a failure to comply with these requirements, though it is always advisable to comply with them. Such recorded proofs are usually made prima facie evidence of the fact that the work was regularly performed whenever such fact is questioned in an action in court.

Resumption of Labor.—The mere failure to perform annual labor does not result in a forfeiture of the claim per se. If work is resumed before an adverse location is made, and continued with reasonable diligence until $100 in value has been performed, the law is satisfied.

The provisions of the statute requiring the performance of annual labor are wise and salutary. Without them it would be possible for a few individuals to locate a major part of the mineral lands of the public domain and hold them indefinitely. The necessity of performing annual labor, slight as the burden may seem, proves in actual experience to be a most effective check on wholesale speculation and permanent segregation of mineral lands from the public domain without development. The law is evaded in many instances, but this is not the fault of the law, but rather of its administration. Many claimants endeavor to hold their claims without performing annual labor, and at the beginning of the new year either re-locate the claims in their own names or in the names of others. By so doing they run the risk of losing their claims, and the courts are inclined to look with disfavor on such trifling with the plain intent of the law. If claimants will perform their assessment work with the bona fide intention of complying with the spirit of the law, instead of going to the other extreme and performing as little work as possible, or trying to credit work of a doubtful nature, they will save themselves trouble later on. Many times a claimant is forced to spend hundreds of dollars in litigation to defend his claim against an adverse location when the expenditure of a few dollars in assessment work would have removed all possibility of questioning its performance. As a final word of caution, whenever a claimant is in doubt as to whether the work done is of the proper character or whether it is sufficient in amount, let him abolish the doubt by doing work that can not be assailed. It will bring peace of mind and save money in the long run.

Calcium is a silvery white metal readily oxidized in moist air. It is very light (sp. gr. 1.52), fairly malleable, has a high specific heat, and is a good conductor of electricity. It is about as hard as aluminum, but at 400° C. becomes as soft as lead. It is volatile, and can be sublimed in vacuo between 700 and 800° C., and melts at the latter temperature. It is a very powerful reducing agent. The most promising applications of calcium are as a reducing agent and for the refining of metals. In the latter case it acts in three distinct ways: by reducing oxides and sulphides; by eliminating dissolved gases; and by forming compounds with certain impurities, thus rendering them less deleterious. All three modes of action are strikingly shown in the case of copper. A suitable addition of calcium will remedy 'dry' or 'sulphur' copper, give a sound casting, and give a soft and tough ingot with prohibitive proportions of bis-muth or antimony, besides restoring ordinary over-poled copper to tough pitch. If excess of calcium is present, however, it induces brittleness on its own account. With one or two doubtful exceptions, no alloy of calcium has shown any promise of commercial utility, so far as physical properties are concerned, its only likely application in this direction being its hardening property.
MINING METHODS IN THE NORTH.—I.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The adaptation of methods to conditions is a basic principle in engineering. While the simple devices of the individual gold digger may seem crude when compared to the technical practice of a scientific operator, the fundamental ideas are the same. In extracting the gold that lies encased within veins of quartz, the elaboration of method has progressed so far as to obscure the essential and elementary principles from which modern practice was evolved, but in alluvial mining the departure has been less marked. Gravel mining continues to be a simple process; not the simplicity of a fool, but the simplicity of empirical deduction. It is the growth of experience in overcoming natural obstacles.

In the North, the mining of gold-bearing gravel has passed through stages of development so complete that the description of them will prove suggestive to technical men, even to those whose duties do not involve this kind of mining. I shall endeavor to trace the evolution of methods that have enabled man to extract an astonishing amount of gold. The creeks at Dawson have yielded $125,000,000 in ten years, the alluvial flats of Fairbanks have given the world not less than $32,000,000 in five years, and the golden beaches of Nome have contributed fully $22,000,000 in eight years.

This gold has come for the most part from deposits of gravel lying in or beneath the beds of existing streams, meandering within the limits of shallow valleys. In order to simplify my analysis of the methods by which the gold was won, I shall take a typical example: A small valley overlooked by rounded hillslopes is traversed by a stream the present bed of which is only a few yards wide as compared to the channel, half a mile across, over which it meanders. Bare ground, in the form of gravel, is visible only on the edge and in the bed of the little stream; the remainder of the valley is covered with moss, out of which arise clumps of spruce, some of them more than a foot in diameter. On the hillsides the forest grows scantier, and on the summits the ridges are silhouetted in sweeping lines unbroken by any trees. A few specks of gold are found in the gravel, and there are rare spots where the rim shows coarse 'colors.' The bedrock is probably a soft schist, for that is the formation exposed in the few places where landslips reveal a section. The prospector cannot sink a pit or shaft in the bed of the stream because of the water that drowns his workings. No pumps are available, nor is it feasible to divert the creek by means of a wing-dam, because that would bank the water on another man's claim; moreover, the gravel is so clean and so porous that the water would penetrate into any workings sunk in the bed of the stream. Thereupon the prospector turns to one side and digs into the valley-bottom at a safe distance from the present stream-bed. He finds that under the moss the ground is frozen solid; it is impossible to sink a shaft with a pick, and expensive to do so with explosives. Yet he reasons that the indications point to the existence of gold on the bed of the valley to one side of the present stream, along a course that it formerly followed. What is he to do?

Such was the problem confronting the pioneers in the Yukon and Alaska ten years ago.

Machinery was lacking. The pick and shovel were the only tools available. Wood was handy. What more natural than to overcome ice with fire, to soften the frozen ground by artificial thawing? This was the pioneer's method. He laid his bundle of sticks and made a fire that melted the adjacent ice. In this way he sank a small shaft to bedrock. The work of sinking was done in winter, when surface-water did not impede. After the wood had burned so as to soften the ground, he broke the latter with his pick and hoisted it to the surface in a bucket with a windlass. Then he piled the gravel near the shaft's mouth in a heap, which re-froze during the winter and thawed naturally in the spring. As it thawed, he shoveled it into a sluice-box and washed it by the help of any water available. His whole equipment consisted of a pan, pick, shovel, a bucket made out of a whiskey-barrel or a hide, fire-wood, a hemp rope, two or three sluice-boxes each 10 or 12 ft. long, and muscle, and more muscle, and persistence. It is wonderful what some of the Alaskans accomplished. Thus Sam Samson and a partner, in the winter of 1901-02, sank a shaft 115 ft. on the Cyrs Noble claim, near Nome. The shaft was only 2 by 4 ft. It was on the 'tundra'. There was no forest to yield good firewood, but Samson found scrub willows near-by and he burned them. He would fill a gunny-sack with willow twigs, dry them in the oven of his stove, and place them in the bottom of the shaft, under cover of a wash-tub, to retain the heat. A fire in the morning and another in the evening sufficed to soften the frozen gravel. He had to conserve the air in his shaft as best he could. He worked in his undershirt, perspiring while the air at the surface was below zero. After sinking 80 ft. without the safeguard of timber, he cribbed the shaft to the surface with inch boards. This was an exceptional case, but it illustrates that grit can overcome gravel, even when frozen. Usually, as at Dawson or Fairbanks, there is a small growth of spruce, quite sufficient to yield the firewood needed for thawing. Usually also the prospector's shaft is not so deep as Samson's. From 30 to 50 ft. is typical.

The gold is found concentrated upon the bedrock. This concentration is more complete in Alaska and the Yukon than in other mining regions; it is due to the clean character of the 'wash', that is, there is so little clay in the gravel that the descent of the heavy gold has not been hindered. It has fallen to the rock-bottom and lies there, sometimes so thick as to be more gold than dirt. In most cases the miner finds his 'pay' confined to the stuff that lies for a couple of feet above bedrock, and within the bedrock itself: for the gold has sunk into the crevices of the rock, penetrating sometimes three feet, if the schist is blocky and shattered. Therefore the operation of mining includes the removal of the bottom...
of the sediment on the creek-bed and the top of the rock-bottom. From 2 to 6 ft. of material is considered rich enough to be treated as 'pay' and is washed in the sluice-boxes.

While I speak of the rock-bottom, it must be explained that the bedrock is usually soft. It has undergone disintegration; it has been shattered by alternations of frost and thaw, in a by-gone time; it has been penetrated by water and some of its constituent minerals have been so dissolved as to leave it no longer hard and resisting, but docile as clay. The soft, almost 'mushy,' bedrock of the North is a great aid to the miner. He does not need explosives.

When the shaft reaches bedrock, it is an exciting moment. The miner scans the ground to find specks of gold; if the gravel is rich, he can see the gold readily. Then he hoists some of the soft bedrock and the fine sediment that lies on its surface. By the use of a pan he washes that material and ascertains how rich it is. Often he sees a glittering string of yellow particles in his pan; sometimes a piece big enough to be called a 'nugget'; sometimes—nothing, but a little black sand, consisting of the magnetite that is the companion of gold. As an illustration of the extraordinary richness of some of these deposits, I quote the following: In August, 1899, on No. 2 Above Discovery on Bonanza, adjoining the Dick Lowe fraction, George T. Coffey took two shovelfuls, that is, enough to fill a pan, and from it he washed 63½ ounces of gold. This included three pieces worth over $100 each. It was possible to see the gold in the gravel when standing 20 feet away. Among those present on that occasion was Angelo Heilprin.

Ordinarily, 10 cents worth of gold, or 2½ grains, per pan, indicating a yield of $13.50 per cubic yard, say, one yard deep, was rich enough to yield a handsome profit to a man who sank a shaft 40 ft. to bedrock.

If the shaft does not 'bottom' in pay, the prospector begins to explore laterally by digging a gallery or drift, following the surface of the bedrock. The shaft may be off the line of the maximum concentration—it has been sunk to the rim of the channel rather than the gutter—and a short drift will enable the miner to find better stuff. Whether he explores for richer pay or opens out into a beautiful layer of golden sediment, he extends a drift from the bottom of his shaft and removes the ground by thawing with fire, as he did when sinking. The removal of gravel by hand-labor in this manner is called 'drifting', as against methods in which water is the prime agent.

The thaw affects only a small patch of ground; it does not endanger the worker, who burrows patiently under a hard roof of frozen gravel. Bit by bit all the gold-bearing dirt within the boundaries of the claim is excavated and raised to the surface, to be washed in the sluice-boxes whenever water is available. This method of working frozen ground by thawing with wood fires was originated in the Forty-Mile and Circle districts before the discovery of the Klondike. Even where timber is cheap, it is more economical to exploit frozen ground in this way than to operate in thawed gravel. At Nome, it is estimated that the economic limit of working thawed ground (on the Third Beach, for example) is reached when the yield is 4 cents per pan, or $5.40 per cubic yard, for a depth of 3 ft., that being the usual thickness of the 'pay' concentrated on the bed-

*Lower Dominion Creek, Yukon.*
rock, which is 70 ft. below the surface. In frozen ground the best record is 1½ per cent per yard; this was the operating cost only, but it included thawing, mining, hoisting, and washing the gravel.

In the days before Columbus discovered America the ancient miners of central Europe employed the method known as ‘fire-setting’. A big wood fire was built close to the face of a level, and when the rock had become thoroughly heated it was customary to throw water on the hot surface so that it cracked. When thus fractured, the ore was extracted by the farther aid of hammers and wedges. According to Henry Louis, this method was in use in the Sala mines, in Sweden, as late as 1876, and in the Kongsberg mines, in Norway, it was employed up to 1884, when improvements in blasting caused the abandonment of the ancient practice.1 I have seen many a face of an old level in the Alps, on the border of France and Italy, that was beautifully coneeave by reason of the application of this method. On the other hand, in the copper region of Michigan, the country is occasionally covered with a blanket of sand, wash, or gravel, which must be penetrated before the hard copper-bearing rock is reached. Sometimes the shaft breaks into a quicksand, making further sinking impossible in the ordinary way. Then artificial freezing is employed; the wet sand is frozen solid and kept in this condition long enough to allow the miners to make the necessary excavation and timber it securely. Thus man uses fire and frost, air and steam, wood and iron, in his subterranean operations, overcoming Nature in one place by the use of the very force she uses to resist him elsewhere.

Wood fires make smoke. The gases liberated are injurious to health. In the North, men soon learned to keep away from the shaft or drift until natural ventilation had purified the air. At best they had to work in a warm moist atmosphere, for they had to excavate the rock softened by thawing before it froze again. At surface the air might be 20° below zero; in the mine the conditions simulated a Russian bath.

After the pioneers in the North had used wood fires for thawing during one winter season or more, a clever operator hit upon the idea of employing steam for the same purpose. Then the ‘steam-point’ was introduced. It happened thus: In 1898 C. J. Berry discovered that steam could be directed to thaw frozen earth. The steam escaping from the exhaust of his engine had thawed a hole in the solid ‘muck’. Berry noticed this and picked up the exhaust pipe, which was a rubber hose. On applying it to the frozen ground he found that it would thaw the muck so as to penetrate for the full length of the hose within a few minutes. This excited the men who happened to be watching the experiment. All of them at once began to devise a scheme for doing this work effectively. Thus the ‘steam-point’ was invented. A rifle barrel was chosen, then a small hole was bored into one side so as to admit the steam.

This was then driven, with gentle taps, for its entire length into the frozen ground. In its rudimentary form the steam-point was a short length of iron pipe, pointed at one end, and attached to a length of rubber hose, through which steam traveled from a small boiler at the surface. The boiler was of the ‘porepine’ type: a hollow shell with water-tubes projecting radially inward, through which the flames pass. The pointed end of the five or six feet of iron pipe was inserted into the frozen gravel and driven forward gently by taps from a hammer, as the ground was softened by the steam issuing from the orifice at the lower end. As finally developed, the steam-point became a specialized tool of great efficiency. A solid head was added to the end that is hammered and a protecting ring was welded to the forward end: the shank itself was made of hydraulic pipe of the strongest kind, and armored rubber tubing replaced the ordinary hose. The length of the ‘steam-point’ ranges from 6 to 16 ft., the usual size being 8 ft. This is driven home so as to make a hole about 6 ft. deep. The accompanying sketch will illustrate the details of construction. The hole in the steel head allows for the insertion of a bar, wherewith the point is turned so as to aid advance. As the operator hits the head with a hammer, he turns the point by means of a bar held in the other hand. The steel head is solid. The ring at the working end is welded on. The hose is attached at the inlet.

As used two or three years ago, the cost of thawing was 25 to 30¢, per cubic yard. With longer points, longer sweating, cheaper fuel, better system, the cost has been reduced one half. In a 20-ft. deposit, using 12 to 13-ft. points, it is possible to thaw 3½ to 5 cubic feet per point at each setting. One of the first to use the method systematically was J. M. Elmer, who erected a rough plant on the Discovery claim of Bonanza creek in the winter of 1898. He had two boilers of 50 hp. each, 60 points, and hose to transmit steam 25 to 100 ft. from the boilers. His points were 14 to 16 ft. long, that is, they sufficed to reach bedrock at that place. There was 4 ft. of frozen muck on top of the gravel. Each point thawed 5 to 8 cubic yards per 24 hours, the poorest work being 3 ft. square of bedrock to a depth of 15 ft., or 135 cu. ft., equivalent to 3 cubic yards.

Expenses per 24 hours included:

| Wood—5½ cords, at $13.50 | $74.75 |
| Labor—5 men on two shifts | 40.00 |

The thawing amounted to 400 cubic yards, so that
the cost was 28.5c. per yard. The plant cost $4000. Each point used steam equivalent to 11 2 horse-power. 2

The efficiency of a point will vary according to the pressure of steam, the length of the tool itself, the distance between the points, the time allowed for sweating, and the amount of moisture in the ground. An effort is made to fix the intervals between points so that their spheres of influence do not overlap. By allowing the steam sufficient time to do its work, the area affected is increased. This is the 'sweating' stage. As the amount of humidity, in the form of ice, increases, more steam is required to overcome the latent cold. The 'muck' that covers the surface consists of 75% ice and 25% organic

wood fire and windlass. Then came the 'steam-point.' In June, 1898, Clarence J. Berry put the first steam-scraper to work; his plant included a 4-hp, Atlas engine and a porcupine boiler, which had been used to propel a scow down the river. In the same year Berry also erected a boom-derrick on No. 3 El Dorado. This was the first rig of the kind erected in the Klondike district. By the aid of this derrick the gravel was hoisted to the sluice-boxes, with a saving of 50% in the cost of operation.

In the early days of mining in the Klondike, when the frozen ground was conquered with wood fires, the 'creeks' must have looked like an inferno. If you had gone up the narrow valleys of Bonanza and Hunker during the long twilight of the arctic winter

Cleary Creek, Near Fairbanks.

matter. A large expenditure of steam is needed to make the thawing effective.

When the steam-point was introduced, the extraction of gravel from the drift-mines was continued in summer, as well as winter, and the production of gold proceeded concurrently, as long as the weather at the surface permitted. The dump accumulated in winter would freeze before spring, necessitating the employment of steam-points before it could be moved. Moreover, the boiler erected for the purpose of thawing was also used for hoisting. Larger buckets and a bigger scale of operation became possible.

During the first three years, from 1896 to 1898, at Dawson, the mining on the creeks was done by

1 For these data I am indebted to Mr. A. J. Beaudette, the Territorial Engineer at Dawson.
AMALGAMATION METHODS.
Written for the MINING AND SCIENTIFIC PRESS
By H. W. MacFarren.

There is found a wide divergence in the ideas and methods of different amalgamators, and the subject of amalgamation should receive more attention, especially in these days when leaf-filters, all-sliming, and crushing in solution are so much in vogue. Amalgamation, where possible, is the money-making end of milling gold ores; yet men of technical attainments are passing it by lightly. Rarely do we find a college graduate serving his apprenticeship today on the battery. There are those who advocate fine grinding of the original ore for cyaniding, but, as some South African metallurgists have said, if we allow a flake of gold to pass the plates and go to the cyanide plant, we can get only 95% of it, as against the total we would have if caught on the plates. We are advised that with the new filtering devices we should be able to save close to the dissolving limit, but those who have seen the many bad and ruined charges, the leakages and runaways, and the accidental washing with a 'wash-solution,' the stock of which builds up so rapidly in value that it must be sent to the zinc-boxes every two or three days, are still unconvinced that it is not best to catch as much as possible by amalgamation.

A striking difference is found in the condition of the plates as maintained by different amalgamators. Some keep the apron-plates quite hard, even to the verge of the amalgam breaking away, and the lower plate becoming blue, for the purpose of preventing the quicksilver from working down the plate into the mercury-trap and eventually into the creek below. Others keep the amalgam soft and plastic, sometimes overfeeding quicksilver to the extent of working down and off the plate and so becoming lost. A coarse, easily amalgamable gold will be readily caught on a hard plate, but fine gold requires a soft plastic bed of amalgam. Whisk a particle of hard amalgam over a hard, dry amalgamated surface and it will probably not be caught; then brush it over a soft wet spot and notice how quickly it catches. We have an analogy in nature, in the case of a snowflake blown across a sheet of ice; given a sheet frozen hard and the flake will not catch, but given a soft plastic sheet, on the verge of melting, and the flake will easily be arrested. If the sheet of ice were inclined it would be in the same position as an apron-plate, and by keeping them soft we have the best catchers, but if we overstep the narrow margin of safety the water or the quicksilver will run off, carrying with it the precious flakes with which it has combined—and here is the difficulty with soft amalgamation. Given an easily amalgamable ore, the mill-man may incline toward hard amalgamation, and save the greater attention and time required when soft amalgamation is practised.

Careful amalgamators who use considerable refinement in their methods, dress the apron-plates with a rag, taking a little amalgam off daily with the rag, entirely eschewing the use of a rubber, and taking no more on 'clean-up' day than at any other time.

They keep a good bed of amalgam on the first plate, and less on the second; after rubbing the quicksilver well in and getting an even texture across the plate, with any surplus amalgam pushed up to the head, they smooth down the amalgam by rilling or reaching across at right angles to the flow of the pulp, with a whisk-broom. They aim to feed quicksilver hourly through the mortar, in such a quantity that very little will be needed in dressing the plates, and yet not enough to cause the brush lines to run or disappear. The amalgam on the upper apron-plate should be of such a consistency that it can be pushed up with the finger and remain without flattening out. In appearance this amalgam should look neither hard and dead, nor like a mirror, but should have a white frosted surface. The lower plates should be watched. The quicksilver and amalgam should not run down upon the lower plates. When any gold is caught on the last apron-plate, investigation is necessary. The practice of rilling or reaching across the soft amalgam has been condemned, on the ground that these rilles catch the fine iron and steel and the sulphides. The fact that these tiny grooves do this speaks well for their function in catching gold. However, these rilles can be avoided by smoothing down the amalgam with a fine-haired paint or kalsomining brush. Care should be used that all the particles of amalgam are bedded down.

Chisels, scrapers, and pumice stone should not be used on apron-plates unless the amalgam becomes so hard that it cannot be removed in any other way, and it is well to avoid the amalgam becoming as hard as that. Sweating plates is dangerous on account of salivating the workmen. In Australia the laws prohibit approaching a sweated plate until the lapse of a certain length of time, which practically renders the 'sweat' of no avail. Turn up the edges of the apron-plates and slip the ends well under another, and the quicksilver will not work through the table to the floor. Drops between plates are in favor, as the amalgam seems to pile up at the drop; this is mainly due to too much quicksilver being fed, or the plate being cleaned so close that there is no amalgam remaining to act as a 'binder' for the quicksilver. There should be a drop between the first and second plate, but others are superfluous, since but little should get below these plates. These drops interfere with quick dressing of the plates. A drop of one-half inch is sufficient; more than three-quarters is liable to secur. Foundations for the plate tables should be carried up from the ground, so as to be as independent of the mill-jar as possible, as it causes the quicksilver to separate out of the amalgam. In starting a new plate, run some low-grade coarse gold ore through until the plates take on a layer of amalgam. New plates washed with quicksilver do poor work, and consequently 'skin-tight' clean-ups should be avoided, unless some of the amalgam is returned to the plates.

Occasionally a man is met who takes the amalgam off his apron-plates only monthly or semi-monthly, who has a water-drip at the head of them, and who has his amalgamators feed quicksilver by a chart. With him is likely to be found the man of secret
'dopes' and nostrums. Use as few chemicals as possible. A little lye to ent the grease is good, also nitric acid solution for pickling the quicksilver. The quicksilver is sometimes 'loaded' by first freeing from all adhering moisture and then adding metallic sodium in small lumps until the quicksilver just commences to amalgamate a bright nail. It is but little used by practical mill-men, as it renders the quicksilver so active that the amalgam freezes to the iron or steel surface of the mortar, while so much fine iron and steel and sulphide are caught by the plate-amalgam that these surfaces become foul. It can be used to advantage in starting new plates or in covering bare spots. Cyanide appears to do more harm than good; being used as a strong solution, it is injurious to the hands of the workmen, allows the quicksilver to be rubbed into the coper, and the benefit it gives is only temporary, as the plate eventually becomes still harder. Plates that have been continually treated with a strong cyanide solution are difficult to handle, especially if little amalgam is kept on them, and that in a hard form. This trouble is manifested mainly by the quicksilver coming out in globules and running down the plate. Bare spots are often treated by softening with strong cyanide solution and then rubbing amalgam in, but in most cases the spots are soon bare again. It appears better to cover the bare places by coaxing the deposition of amalgam from the edges toward the centre, just as nature covers an open wound by growing the skin or bark from the edges of the cut to the centre. To do this, brighten the coper by burnishing with a little fine grit and then pushing the adjacent amalgam over and rubbing it well in.

The tail-box of all apron-plates should be fitted with what is known as a 'treasure box'. This is simply another compartment in addition to the one collecting the pulp for the launder; a swinging lid or door enables the pulp from the plates to be directed to either compartment. The plate is washed down with a heavy stream of water, preparatory to dressing, into this second compartment; after dressing, the plate is again washed down, this time with a light stream. The function of the 'treasure box' is to catch the particles of loose amalgam that might otherwise be lost, and also the rich sulphides that have attached themselves to the plate by reason of the amalgamating of an exposed face of contained gold. This box is very necessary when running on rich ore. A portable trough that can be temporarily placed below the edge of the plate is sometimes employed.

The use of inside plates is a matter of individual preference. Some claim they should not be used; that they place the amalgam where it can easily be secured off and lost, should the mortar overfeed. Others claim that in some cases fine gold can be caught by their use, that cannot otherwise be saved. All are agreed they should not be used if the same saving can be made without them. It is usual with many amalgamators to use an inside plate when running on rich rock, with the idea that the less the amount of amalgam to be handled on the plate, the less the loss will be. The common form of a curved chuck-block is wrong, as the curved part, or belly, is in an excellent position to be secured; on opening a mortar that has run choked for some time it will often be found that this upper curved part is secured, sometimes down into the copper. Take a 2 by 6 in. piece of sugar pine and rip it diagonally across the end, making two triangular sectional lengths; attach one of these to the usual strip that rests in the screen-slot by bolts a foot or more apart, using a strip of iron in connection with these bolts, to hold the lower edge of the copper-plate in position, and as a protection against it becoming torn loose. Scouring can largely be prevented by protecting the plate with a No. 4 mesh screen of heavy wire, spaced from the plate by a nut on the bolt which attaches this screen to the chuck-block. A back-plate can be used in a narrow mortar, if it can be set 6 in. above the dies, and bolted through the mortar. This plate should have two sets of bolt-holes, so that it may be adjusted to the wear of the dies. Inside plates must be carefully watched, especially on starting, and no bare spots must be allowed; they tend to spread like a rotten spot in an apple. At all times the feed must be kept just right. They should be kept hard, using the lip-plate as the indicator in feeding quicksilver.

The lip-plate should be wide, 12 or 15 in., if possible. Splash and other outside mortar-plates are a matter of individual opinion. There should be as large a surface here as possible. The usual conditions under which work is done today are with a fine-grained gold, a low-grade ore, and a large capacity—necessitating a narrow mortar and a low discharge, thus prohibiting the successful use of inside-plates, or of catching much gold in the mortar-sands. This leaves only the outside mortar or lip-plates, and the apron-plates. The amalgam on the mortar-plates is in a hard form, not likely to run or slough off, and here is the place to hold it—a better place than on the inside plates, but not as good as the mortar-sands. The apron-plates are reserved for catching the gold that has escaped higher up. These mortar or lip-plates are scraped at intervals varying from a few days to a month, according to the richness of the rock.

The mill-man may experiment with a plate in the tail-box, the launder, and on the concentrators, but they must be dressed occasionally. Patent amalgamators to follow plates may be of advantage in some cases, but usually not, as it is the amalgamator's business to see that there is nothing left that can be caught by amalgamation, consequently they should only be put in on trial.

The practice of cleaning the removed amalgam on one of the apron-plates is bad for various reasons, although when the 'treasure box' is used, the loss of gold is small. The easiest way to clean the amalgam is to place it in a large gold-pan with an amalgamated bottom, on removing it from the plates; then, when at leisure, work it up on this amalgamated surface at the clean-up sink, catching the refuse and periodically grinding it up with quicksilver.

Where difficulty is experienced in amalgamating the gold, it is well to increase the grade of the apron-plates and use less water in the mortar. For a coarse, easily amalgamated gold, long apron-plates
are unnecessary, though they may be required with fine gold or where an excess of water is used. Given a long plate, where the gold is practically all caught on the first few feet, there is on a large part of the plate a condition akin to that when running through a large tonnage of poor ore, where it appears that there is not sufficient metal plated to prevent loss, probably by attrition. No exact reason can be given for this poor work with extremely low-grade ore. It is analogous to what occurs in the zinc-boxes when a large volume of solution of low gold content is allowed to run through. This condition may justify using a little rich ore to sweeten the mill-feed. Long plates may be of advantage where a distributing or collecting box at the head of the apron-plate is utilized to turn the pulp down one-half of the plate while the other half is being dressed, thus saving the labor involved in hanging-up and the loss of duty from stopping the battery. Every mortar should be built so that one of these boxes can be bolted to it, if desired, as they are convenient for using a wide lip-plate. They distribute the pulp evenly across the plate in case of an irregular discharge from the mortar due to the bad order of drop or to other cause. They also form a projecting lip over the plate-table, preventing leakage, and they reduce jarring of the table by close contact with the mortar. Where no distributing-box can be bolted to the mortar, the plate-table can be set a few inches below the mortar-lip to permit a wooden box being inserted for catching the flow. At the Empire mill, at Grass Valley, the tables are fitted to the mortars in this way, and when dressing a plate, a trough of sufficient length to carry the flowing pulp to the plate of an adjacent battery is used. These methods should only be practised if tests show that the tailing is only a little higher while the plate is carrying an overload.

With individual stamps, outside amalgamation is usual, although quicksilver has been successfully fed to the mortars. As these stamps require much water, a half plate should be fitted to each stamp, or a full-width plate to two stamps built together. The placing of two plate-tables to take the pulp from three individual stamps built together has not been a success on account of the inability to distribute the pulp evenly across the width of the plates. Too often in outside amalgamation the plates are dressed too wet, and then allowed to become hard before dressing again. This trouble can be avoided by sprinkling a little quicksilver from a bag or bottle upon the dry spots at the head of the plate, without stopping the battery, but it must be done carefully. Outside amalgamation is interesting and offers excellent opportunity to study plate-work. On many ores it will be found possible to stop nearly all the gold on the first 12 in. of the upper plate, if quicksilver is dropped upon it as needed. When quicksilver is not supplied as required, and the plate becomes hard and coated, as when treating rich ore, the gold will tend to slip over and be caught farther down, while if too much quicksilver be used, the amalgam will run down, which is probably worse.

Amalgamation in cyanide solution presents no difficulties, within the requirements made of it. As the solution usually does not exceed one pound per ton in cyanide strength, it does not cause the plates any harm. Neither does it injure the hands of the workmen, though it may make them rough at times. A good remedy for this is to rub Albany grease into clean hands, and to work with gloves so as to allow the grease to remain on as long as possible. As the life of plates in solution is limited to from six to nine months, the devising of means for prolonging their life offers an excellent field for investigation. With silvered copper plates costing approximately $2 per sq. ft., the item for renewals is important. When amalgamating in cyanide solution, the plates will be eaten through in spots, and yet it may not be convenient to put in a new set; consequently it is necessary to build plate-tables that will prevent the quicksilver from working through. This can be best accomplished by using 2 by 4 or 4 by 4 in. planed, well seasoned lumber, the length of the table, put together with tar of paraffine paint, and bolted tightly across the width of plate every 3 ft. If drops are used, do not allow the edges of the plates to project beyond their wooden backing, as they are gradually eaten down to dangerous knife-edges.

Radium.—The difficulties attending the estimation of radium in rocks and other materials leave still a large balance of certainty—so far as the word is allowable when applied to the ever-widening views of science—upon which to base our deductions. The emanation of radium is most characteristic in behavior; knowledge of its peculiarities enables us to distinguish its presence in the electroscope, not only from the emanation of other radio-active elements, but from any accidental leakage or inductive disturbance of the instrument. The method of measurement is purely comparative. The cardinal facts upon the strength of which we associate radium with geological dynamics, its development of heat, and its association with uranium, are founded in the first case directly on observation, and, in the second, on evidence so strong as to be equally convincing. Recent work on the question of the influence of conditions of extreme pressures and temperatures on the radio-active properties of radium appear to show that, as would be anticipated, the effect is small, if indeed existent.—John Joly.

No one factor has contributed more to America's industrial supremacy than the rigid policy of 'scraping' out-of-date machinery. If a new form of motor comes out tomorrow, in the use of which the power bill is cut 10%, the consumer, and the engineer who advises him, want to know all about the motor immediately. The advertising display draws the first attention; it is filed, and correspondence then brings further data. The policy of 'scraping' what is obsolete in machinery has a close parallel in what an engineer should do with the record of obsolete practice that fills his library. The step advocated, standardization, will make the process of weeding out and 'scraping' the easier and simpler; the obsolete can be put aside in separate binders on the top shelf.
OIL PROSPECTS IN NEVADA.

During the early part of November, 1908, an examination of the oil prospects in Nevada was made by Robert Anderson, of the U. S. Geological Survey. We are in receipt of his preliminary report:

The hills west of Reno, to the north and south of the Truckee river, are composed of a thick series of unconsolidated beds of sand, clay, diatomaceous earth, volcanic tuff, and gravel, dipping eastward and northeastward away from the mountains at angles of from 15 to 35°. These beds have been called the Truckee beds. They overlie andesite lava and older igneous and metamorphic rocks, such as form the mountains to the southwest and northwest, and were laid down upon them as sediments in a fresh-water lake that covered much of this portion of Nevada during Middle Tertiary time, when the region was much less mountainous than now. Subsequent to the deposition of these beds, mountain-making forces had produced the surrounding mountains and had tilted the beds up into their present attitude, besides fracturing them throughout with an intricate system of dislocations. Later periods have witnessed likewise a great amount of erosion of the mountains and hills, the presence of other lakes, and the deposition of a comparatively thin covering of sand and coarse gravel over most of the hill and valley area around Reno.

If petroleum were present it would with little question have to be considered as originating in the Truckee beds, and there, if anywhere, it would be stored. The examination of these beds has resulted in the conclusion that no paying quantity of petroleum, if any at all, will be found in them, for the following principal reasons:

First. No indication of the presence of oil has been discovered in the beds at the surface, although they are tilted and the succession exposed as a whole in such a way that some of the oil, if any were present, could hardly fail to escape to the surface and leave a trace. Moreover, the completely permeating system of small fault-fractures would lend further avenues of escape. The supposed indications of oil that have been reported by previous observers are iron, manganese, and vegetable stains in certain strata and occasionally on the surface of standing pools of water in the vicinity.

Second. The structure of the beds is that of a monocline of considerable dip, at the base of which the oldest beds of the formation are exposed overlying the volcanic rocks of the mountains. The summit of the antiplanal fold, which probably once arched over toward the west into the southwest-dipping strata of the Verdi region, and which would have afforded the best conditions for the accumulation of oil, has been completely removed by erosion. The tilted, erosionally truncated, and intricately faulted condition of the strata would favor the diffusion and escape of the oil, if any were present, rather than its accumulation in large quantities.

East of Wabuska, the examination was confined chiefly to the basin-like valley in which the Yerington Oil & Gas Co. is drilling a well, north of the great northerly bend of the Walker river and about eight miles eastward from Wabuska. This valley is typical of a number of similar basins in this region that form elbows in the valley of the Walker river.

The basin is surrounded by mountains formed chiefly of lava and volcanic fragmentary matter, and has a fairly level floor with surface covering of loose sand and compact clay. Horizontal strata of unconsolidated sand and clay, and detritus from the mountains, have accumulated in this basin within a comparatively recent (Quaternary) period of geological time, probably nowhere to a depth exceeding a few hundred feet. The shallow and local nature of this filling is indicated by the fact that little knolls of the lava that forms the bedrock of the valley, occasionally rise above the floor, in some cases very near the river. The chance of finding oil in this vicinity must be considered very slight, for the reason that there is no evidence of the presence of any strata that might be looked upon as probable oil producers.

The portion of Smith valley that was visited was the northern part, extending from a line drawn eastward across the valley from Hinds' Hot Springs northward to Bueskin. The mountains on the east of Smith valley are formed chiefly of much altered limestone intruded by granite and rhyolite and capped with andesite lava; those on the west, chiefly of granite and porphyritic igneous rocks. The valley itself contains a filling of horizontal lake-beds of unconsolidated clay and sand, which are exposed in low bluffs at the edge of a terrace on the side of the valley. These beds probably belong to the late Tertiary period, when a lake must have covered the valleys of this region. The beds do not date so far back as those in the vicinity of Reno. They are locally overlaid by talus and alluvial fan deposits at the base of the mountains, and by a comparatively thin coating of recent sand and clay deposits that have been laid down over the floor of the basin. No definite estimate can be made of the depth of the sediments in this valley, but it may be said that they are probably underlaid at a depth of not very many hundred feet by the volcanic rocks or older bedrock series. The geological character of the region is not such as to favor its selection as a possible petroleum producer.

A brief examination was made of an asphalt prospect in northeastern Nevada, about 15 miles south of Palisade, near the foot of the mountains east of Maples' range, on the Eureka & Palisade railroad. At this locality a lustrous black asphaltite, resembling in character the variety called imposante, occurs in veins and stringers along fracture planes and as sheets along bedding planes in well indurated calcareous and clay-shale and sandstone beds of Carboniferous age. The lenses of asphalt are variable in size and occurrence. The greatest width of any ore observed in the prospect openings is about 18 inches. The asphalt cannot be traced on the surface of the ground, but similar material occurs at different points several miles distant, and it is probable that the zone of fracturing in which it has collected has considerable extent.
Decisions Relating to Mining.

Improvements on One Mining Claim No Aid to Others. The sum of $132, allowed for improvements on one mining claim made in a year, was sufficient to prevent a forfeiture of such claim, but would not prevent a forfeiture of other claims in a group, upon which no improvements were made.

Fredricks v. Klausen, (Ore.) 96 Pac. 679, July, '08.

Location of Mining Claim—Discovery. To constitute a valid location, there must be such a discovery of mineral as that an ordinarily prudent man, not necessarily a miner, would be justified in expending his time and money thereon, in the development of the property. While mere possibility that ground claimed contains gold, or that there are mere indications of the existence of minerals in the ground, is not sufficient to justify a prudent person in expending money and work in exploration of it, yet where the evidence shows the actual existence of gold in the claim, the locator is entitled to strengthen the proof upon any of the elements which enter into what is comprehended by discovery. He may supplement the showing that mineral actually did exist, by proving, as a ground of justification for the expenditure of money and time, that the adjacent ground in the same gulch is rich in the same material. If a combination of adjacent claims were developed into paying mines after development upon similar showings of mineral, or that geological conditions are so similar that, from the character of the mineral discovered, it is reasonable to expect to find mineral in valuable quantities in the exploitation of the alleged claim. But there must be an actual discovery of mineral within the limits of the claim before a valid location can be established.

Subscription to Mining Stock—Payment—Recovery. A purchaser who paid cash for shares in a prospective mining corporation, where the project was finally abandoned after an adverse report by experts, had no right to recover the sum paid, where all the parties treated the stock to which they would be entitled as the measure of their interest in the venture.

Clark v. McManus, (Minn.) 117 Northwest. 476, July, '08.

Mining Company—Purchase of Mining Ground. The statute of California prohibits a mining company from buying any additional mining grounds without the approval or ratification of the stockholders. Under this statute, in order to raise the question of the validity of a purchase by a mining company, it is necessary to prove that the land purchased was additional mining ground.

Oil Lease—Nature and Construction. Oil leases stand on a different basis from ordinary leasehold agreements, for the reason that the work which is to be done is orderly and speculative in nature, and if oil is not found no estate vests in the lessee. The rule that forfeiture or abandonment is not looked upon with favor is not applied to an oil lease.

Oil Lease—Abandonment. Under an oil lease for 15 years, and as long as oil should be found in paying quantities, the lessee drilled a well but found no gas; he afterward removed all the drilling machinery and tools, except the casing in the well, and did no other drilling for more than ten years; this was held to be an abandonment of the lease.

Commercial Paragraphs.

L. H. Wygant Jr., is with the Morse Bros. Machinery & Supply Co., Denver, Colorado.

The Bausch-Knecht-Heumann Co., San Francisco, announces that its sales for November, 1908, were double those for the same month in 1907.

The Thompson Balance Co. has moved its office and factory to 808 Twentieth St., Denver, Colo., where it will have a new and commodious factory for the manufacture of Thompson balances.

The Luskenheimer Co., Cincinnati, announces that it has recently received an offer from the Isthmian Canal Commission for 79900 globe and angle valves, ranging in size from 3/4 to 3 inches.

The Western Engineering & Construction Co., San Francisco, is distributing a pamphlet containing two good photographs of dredges built for use at Oroville. It is a novel and attractive idea in advertising.

Grant W. Spear, who for many years has been vice-president of the Dearborn Drug & Chemical Works, at Chicago, took charge November 1 of the Eastern offices of the company, at 299 Broadway, New York City, as vice-president and Eastern manager.

Theodore Albert was recently elected president and treasurer of the Wm. Powell Co., of Cincinnati, Ohio, to succeed the late James Powell. The new management has long been identified with the company and will continue to uphold the high character of the Powell Co.'s steam specialties.

The Wagner Electric Mfg. Co., announces the appointment of John Mustard as assistant manager of sales for the East, including Pittsburgh and territory east thereof, with headquarters at Philadelphia. Mr. Mustard has been with the Wagner Electric Mfg. Co., as district manager, at Philadelphia, for the past 15 years.

The Aquatic Mines, Inc., at Quebrada Honda, Costa Rica, via Port Limon, via San Mateo, desires catalogues descriptive of all and kinds of mining, milling and electric machinery and supplies. The plans include a 100-stamp mill, a 2000-hp. hydro-electric power-plant, aerial tram, a four-mile electric tram road, compressors, drills, cars, and all auxiliary machinery.

The Pacific Equipment Co., dealers in new and second-hand mining, railway, contractors' and oil-well machinery, has established offices in San Francisco, Los Angeles, and Scottie. The president, J. W. Pike, for many years has been, and is now, interested in various mining enterprises. The manager is W. A. Desborough, formerly with the West Coast Machinery Co., and the Joshua Hendy Iron Works of San Francisco.

The Sullivan Machinery Co. announces that Sullivan rock-drills, air-compressors, and hammer-drills are now carried in stock at Spokane, Wash., by the United Iron Works Co. The same company also represents the Sullivan Machinery Co. at Seattle, and will carry a stock of drills, compressors, and supplies, at 109 Main street. Austin Y. Hoy is the representative of the Sullivan company in this territory, with headquarters at Spokane.

Catalogues Received.

The C. O. Bartlett & Snow Co., Cleveland, has recently published its Catalogue No. 27, describing screening machinery.

The Wm. H. Hoebee Co., Inc., Los Angeles, is distributing a set of handsomely illustrated catalogues called: No. 12, Guns and Ammunition; No. 14, Tents and Camping Goods; No. 15, Outing Suits and Boots; No. 17, Women's Catalogue—riding, fencing, hunting, and hunting costumes.

The Western Electric Co. has just issued a little booklet called 'Pointers on Power,' which discusses the question of individual machine drives by the use of induction motors, and shows it to be particularly advantageous in places where inflammable dust, gases, or oils are present.

EDITORIAL.

IN ENGLAND, Mr. Andrew Carnegie's later philosophy is contrasted amusingly with his earlier career. The Financial Times quotes from Mr. Carnegie's article in The World's Work where he says: "It is a low and vulgar ambition to amass money." Thereupon our London contemporary is reminded of the small boy who, after a sound chastisement, was thus addressed by his father, "Now, Tommy, understand that this is for your own good. Remember what the great Solomon said, "Spur the rod and spoil the child." "Yes, I know," sobbed the little delinquent; "but Solomon didn't say that till he was grown up!"

TO BE ABLE to select a good foreman is the first step to success as a mine manager. The foreman and the shift-boss do not figure in the printed reports or other records of a mining company, and the average director fails to appreciate the real importance of these humble members of the staff, but, to tell the plain truth, the cost of mining and the finding of ore are largely in their hands. Complete sympathy and cordial understanding between the superintendent and his foreman, as well as between the foreman and his shift-bosses, is an excellent preventive of labor-troubles and a notable stimulus to efficiency in a mine.

TO Mr. J. B. Lippincott and Mr. W. C. Aston belongs the honor of having broken the American record for rapid tunnel-driving. First place had been held by the Gunnison tunnel, in Colorado, the rate there having been 499 feet in one month. At the Elizabeth Lake tunnel, in southern California, a speed of 466 feet has been attained. Even more significant is the fact that this work, constituting part of a municipal engineering enterprise for bringing water from Owens river to Los Angeles, was done far below the estimated cost. The engineers' forecast had been $66 per foot; the actual outlay was $35.81 per foot, with a cross-section 12 feet square.

WE ARE INFORMED that Mr. Edgar Taylor, of the firm of John Taylor & Sons, has been elected President of the Institution of Mining and Metallurgy, at London. The election is made by the Council, which is a representative body, therefore the presidency is properly deemed a great honor. We take particular pleasure in saluting Mr. Taylor as titular chief of our profession; he is well worthy to represent the English-speaking mining engineers, for his own honorable career is the sequel to a family record that now covers the lives of three generations of Taylors. It is not too much to say that the continuity of professional labor and business activity
marking John Taylor & Sons places that firm in a unique position. Mistakes they have made, like other men, but nothing sordid has ever stained their professional reputation, and in a period when men have been willing to sacrifice everything to the mere making of money, this firm has stuck to the right principles inherited from John Taylor and Richard Taylor, grandfathers of the men now in control. There are hundreds of mine managers and engineers in different parts of the world that have been associated, as their fathers before them, with John Taylor & Sons; to all of these it will seem a fit and proper thing that one of that name, and a man that has added lustre to the name, should be chosen as President of the most representative of mining associations.

E D U C A T I O N A L institutions invested with power to confer degrees are under moral obligation to maintain the dignity of those insignia of intellectual labor. Manifestly a college or university that offers courses that do not lead to degrees cheapens the value of its diplomas. The short courses in assaying, metallurgy, electricity, and the like give essentially an artisan training; they educate men not for professional work but for a trade. The place for such instruction is in technological high schools. The artisan is worthy of high regard and he has a right to be considered in the general scheme of education, but he should not be trained under conditions that will confuse him in the public mind with the college graduate.

O U R F R I E N D S of the Institution in London publish much valuable material, and they have done useful service in standardizing technical usage, therefore it is reasonable to expect that the publications of the Institution would illustrate the excellent preachers issued from Salisbury House. They do not. We remember something lately about a standard ton of 2000 pounds. Why then use the 2240-lb. ton? It may be too much to expect that the unnecessary plural, in such words as 'tailings' and 'concentrates,' shall be dropped, but why speak of 'tailing analysis' and of 'the accumulated tailings' on the same page? Also, why should 'Buss tails' be abbreviated unpleasantly while 'Frue Vanner Tailings' suffers no elision? The use of 'head' and 'tail' in analyses of samples from concentrators recognizes the singular idea, which is not as singular as it seems, in virtue of which the unnecessary plural is dropped and a useful inflection preserved. The mill in which these things happened 'consisted of 60 Cornish heads.' That explains it all. Sidney Smith once told the vestry of Islington, when considering the proposal to lay wooden block-paving in their parish, that all they had to do was to put their heads together, and the thing was as good as done.

T H E A D J U S T M E N T of freight rates in an equitable manner is perhaps the most complicated single problem entering into the complex internal economy of the nation. The President has made strong suggestions on this subject which merit the serious attention of Congress. He proposes that the Interstate Commerce Commission should have summary jurisdiction over rates. This seems the only way to enable the Commission to achieve its highest usefulness. In Mexico this has long been the case, but the traffic commission in that Republic is representative of the people and also of the special interests at stake; in other words, the railroad corporations name members of the commission as well as the Government, although properly the Government holds the majority on the board. The most crying need of the people, as also of the transportation companies, is relief from the excessive burden of lower-class freight carried by the railroads, which either commands a higher rate than it should, thus oppressing and limiting industry, or is handled at a price that entails an actual loss upon the railways. The escape from this dilemma lies in earnest promotion of every feasible project for development of internal waterways. The report of the commission, now investigating these possibilities, should point the way to a new era of higher prosperity, for commerce responds directly to every fluctuation in the burdens of transportation costs. By relieving the railroads more and more from the unprofitable classes of freight, industry must necessarily grow at such a pace as to expand the carrying trade in higher-class articles, which can afford to pay remunerative tariffs. In following this line of development we shall only be extending the benefits to the people and to the railroads that have followed the utilization of the great water-route from Duluth to New York; and we shall be profiting by the experience of Germany in the canalization of her rivers; and by the early experience of England in her canal-building period, before she allowed her industries to be handicapped by rates that would cause an American shipper to collapse in amazement.

S m e l t e r S m o k e.

Smelter smoke troubles have assumed a new character in Montana. Usually there is general clamor for the decapitation of the goose that lays the golden egg. In Montana, however, the fumes are accepted more philosophically. It is the Government that appears as complainant, with the President thunder rolling ominously. The forests are of more worth than any other interests, declares President Roosevelt, and he points to the sad plight of northern China and certain of the Mediterranean countries as examples of the irremediable disaster that follows in the wake of deforestation. The soil, with water to render it productive, is the fundamental asset of any community. The mineral wealth of a region must be great to admit of its continuance without the adjunct of agriculture at a reasonable distance. But Montana insists upon occupying a unique position that would absolve her from rigid application of the Presidential rule. The threatened proceedings against the Washoe smelter have aroused earnest protests from the citizens of Butte. They insist that the livelihood of 75,000 people must not be swept away, at least not by summary action. The consequent suffering would undoubtedly be extreme, and
it is gratifying to learn that no precipitate course will be pursued. A commission will be appointed to investigate. Meanwhile the question of supressing the smoke-nuisance should seriously engage the attention of the smelting companies, important and only partly explored phosphate belts exist in Wyoming, Utah, and Idaho. It would be wise systematically to prospect these deposits, in the hope of finding a basis for consuming large quantities of sulphuric acid. At the identical moment when such investigations seem urgently needed, the phosphate areas in the West have been withdrawn from entry and location, under executive order, the avowed purpose being to re-classify the lands in question, in order to restore to agricultural entry such portions as are found to contain no phosphate. This action may be technically defensible, but it can only serve to retard the development of an industry that would afford the smelters an incentive for conversion of fume into sulphuric acid, and by so doing protect great enterprises already established. The only other recourse for the smelters, in an effort to utilize sulphuric acid on a large scale, is to manufacture ammonium sulphate, a salt also useful as a fertilizer. Ammoniacal liquors would be available in large amounts if the coke makers in Montana, Utah, and Wyoming would introduce by-product ovens. Fertilizers are not in large demand in the West today because of their cost. The smelters can produce them cheaply, thereby contributing to the welfare of the farmers in high degree, and aiding the work of beautifying the land instead of rendering it barren.

The Mountain Copper Company, under the brilliant guidance of Mr. Lewis T. Wright, was the pioneer in effective suppression of smelter smoke in America. The problem consisted, as always, in finding a means for utilization of the sulphuric acid produced. Mr. Wright solved it by investigating the phosphate resources of the Middle West, which had hitherto been neglected. A further advance in the application of sulphuric acid was made at these works in the production of lime sulphate containing from 5 to 10 per cent phosphoric acid. Such material, of course, would easily displace ordinary plaster in the local market. The sulphurous acid in the smelter-fume at the works of the Mountain Copper Company at Point Lewis, on San Francisco Bay, has been reduced almost as low as in the smoke from steam-power plants that use California crude oils as fuel. These oils for the most part contain 25 per cent of sulphur, and when burned with 50 per cent excess of air beyond the amount theoretically required they yield a fine-gas containing an amount of sulphur equivalent to about 2.1 grains of sulphuric anhydride (SO₃) per cubic foot. An air-consumption of no more than 50 per cent excess is regularly realized in well administered power-plants today, and tests on marine boilers in service, recently made at San Francisco, showed an excess of only 20 per cent. In such cases the sulphurous anhydride in the fine-gases would be nearly 5 grains per cubic foot. In spite of the success achieved at Point Lewis, the supervisors of Contra Costa county have just passed an ordinance restricting the amount of SO₃ in gases issuing from chimneys to 2.5 grains per cubic foot, and making violation of the ordinance a misdemeanor. The outcry against the smelters is manifestly a popular fad. While smelter-smoke has devastated large areas in many parts of the country, the earnest efforts to abate the nuisance are not appreciated. Anyone desiring popularity is sure of a sympathetic following if he starts a crusade against the smelter. The agitation is often the result of mere personal ambition, sometimes with the hope of graft. Speculators have been known to buy large tracts of land so situated as to be in the drift of smelter smoke for the express purpose of profiting by damage-suits. In Utah the Federal Court permitted the United States Smelting, Refining & Mining Company to operate its plant at Bingham Junction under a limitation of 0.75 part by volume of SO₃ per 100 parts of gas. The requirement of the Contra Costa supervisors is equivalent to only 0.15 part of SO₃ per 100 parts of gas. The British Alkali Regulation Works Act of 1906 places the limit of sulphuric anhydride in chimney gases at 1.5 grains per cubic foot, but copper and lead smelters are exempted from the application of this law, in deference to the need of sustaining those industries. They were not required to achieve the unattainable. The law, however, did include the zinc industry, showing by this discrimination an intelligent recognition of actual conditions in metallurgical works. For conversion into sulphuric acid by the chamber process a steady evolution of sulphurous gases is essential. This is obtained in the roasting of ores, but in the subsequent smelting of copper the gases vary within wide limits in their sulphur content. In zinc distillation no such difficulty exists, and the escape of highly sulphurous gases represents defective control of the roasting and acid-making departments. By the British act, sulphuric acid works are allowed 4 grains of SO₃ per cubic foot in the escaping gases. It will be seen that the regulation was framed as a result of careful enquiry into existing conditions by competent men. The law was not an iron rule to compel a universal observance of ideal conditions, but a well conceived adjustment to the conditions attainable by different industries; it recognized the need of industry as a means for earning a livelihood. In Germany the law is equally considerate of the rights of manufacturers to conduct their business under practicable regulations. Alleged damage must be proved, and the amount of sulphuric anhydride permissible in the air at the point where injury is claimed to have been caused by acid fume is 35 parts by volume in one million.

Agitation against the smelters has become a menace to one of the most important of American industries, and the public has become super-sensitive to the point of fancifying inconvenience where none actually exists. We cannot settle the matter by national legislation, since the right to regulate extends down to the merest petty board of county supervisors, but the United States Government has now an opportunity to render a lasting service in this matter. The complaints against the Montana smelters can be turned into a blessing by the appointment of a com-
petition commission with a representation of distinguished scientists, attorneys, and business men, to investigate the question of damage done and feasible abatement of the trouble in a broad way, not with reference to Montana alone. The findings and recommendations of such a commission, followed by intelligent departmental regulations based upon them for rational protection of the national forests and of the smelting industry, would establish precedents that would settle the controversy wherever it has existed. These regulations would speedily become crystallized into case-law and set a limit beyond which local officials would not dare to go, as well as setting a barrier against unjust injunctions issuing from the lower courts. It would give the smelters a chance to live without being outlawed.

The Panama Canal.

Panama has always been pestilential. It has been a breeder of disease, physical and moral—we had almost said intellectual—since the days of Balboa. We can expend more millions on river and harbor improvements than are needed to build the Panama canal, and do it quietly, honestly, efficiently, but as soon as we touch Panama we are inoculated with the old distemper. Mr. William Nelson Cromwell has laboriously replied to his critics, but he has dis- pated no suspicions. To be sure, we may be exceeding our privilege to enquire what sum the New Panama Canal Company distributed in liquidation to its shareholders. It doubtless gave them what was left after settling with the original company, paying its attorney, and providing for other unmentioned and probably unmentionable expenses involved in foisting its moribund concession and insignificant assets upon the Government of the United States. It is something of an impertinence to ask what the New Panama Canal Company did with the money. That is why we suggested that Panama even affects the intellect: the critics themselves lose the scent. What we may justly enquire, however, is the cause of that complacency in official circles at Washington, which led into the original engagement to pay $40,000,000 for what could have been bought in the open market for $5,000,000. We cannot forget the indecent haste with which the United States welcomed the piling infant Republic before it had been properly clad in the garments of statehood, nor that solicitous cale- gram from the State Department to the midwife, on the day preceding the great event. When the Govern- ment of the United States becomes so eager to learn of a revolution that can be made effective only through its protecting power, none but an unsophisticated child can doubt the presence of those evil influences whose persuasion consists in the corrupting use of money. Evil odors have been noticeable whenever the Panama matter has been probed, however lightly. If we desire a first-class scandal to furnish 'sore' head-lines for the daily newspapers, manifestly a congressional investigation of the Panama imbroglio will produce it. We shall feel humiliated by the details of intrigue to establish an opera-bouffe republic, and the unblushing disregard of the Dick-

inson-Ayon treaty, entered into with Colombia to protect her against that very dismemberment that we ourselves finally effected. Most likely certain representatives of the people 'in Congress assembled' will feel called upon to emulate the recent example of Senator Foraker by taking shelter under technicalities and making explanations that do not explain. Perhaps, too, we shall at last learn the details of that corruption which led to the withdrawal of Mr. John F. Wallace from the control of operations on the Isthmus, with the President, as usual, under instigation from his friends, firing hot shot in advance of proper judicial enquiry. Perhaps, even, we may learn why Mr. Lewis M. Haupt, the most capable member, from an engineering standpoint, on the commission appointed to report on the alternative routes, abandoned his objections to Pan- ama, that the report might be made 'unanimous'. We do not impute corruption to Mr. Haupt, for the world knows that he is superior to base allurement, but we believe that, instead of following the dictates of his judgment, he wavered in his obligations under an appeal to patriotism, and was diverted to the oblique path under representations that it would promote the good of the greatest number.

That engineering difficulties exist at Panama no one can deny. The engineers cannot state that they know all the conditions to be met in building the great Gatun dam. There are rumors of vast slides into the cut on the mountain section: we recall that M. Charles de Lesseps encountered the same difficulty, and wrote a pathetic letter to his father on the subject. He did not see how he could take care of a whole mountain that persisted in sliding into the excavation.

But we are committed to the Panama canal. With all the scandal, and all the difficulties, and regardless of cost, we will have it. We must have it to relieve the trade-tension between the East and the West, to establish that commercial equilibrium which can only result from cheapening the transport of low-priced bulky commodities, between the Atlantic and Pacific States. The political solidarity of the Union requires that one portion shall not be overwhelmingly devoted to manufacturing and another essentially to the production of raw materials. The financial and political welfare of the nation necessitates a distribution of industries. Until there can be cheaper exchange of goods on which time in transit is not of prime importance, the West and the East must be out of balance in an industrial sense. The trans-isthmian canal will correct this, and the duty of Congress is clearly to forward the enterprise by liberal appro- priations. Though miasm may arise upon stirring the morass of past intrigues, the present work must not be entailed. Investigation is proper enough, but the digging must continue. The canal can be built, the difficulties can be overcome; our engineers have the wit and skill to triumph over natural obsta- cles, if the financial sinews be given with sufficient liberality. Let it be understood that an enterprise of this kind must be pushed unremittingly on an ade- quate scale, or what has already been done is as good as wasted.
Personal.

Personal men are invited to send news of their engagements and travels. Such news is interesting to friends.

F. W. Baker is at New York.

J. Morgan Clements is at Colton.

Walter Fitz is now at Salt Lake.

W. F. Ferrilke is on his way to New York.

D. W. Bumby was at New York recently.

Thos. H. Leggett is at Oroville, California.

Thomas H. Starns, of Denver, is at New York.

Barrett L. Thane has returned to Juneau, Alaska.

Albert Herch has returned from the Occen d'Alene.

George T. Coffey is expected at Seattle from Dawson.

E. Sleeveln Marks is on his way to the Malay States.

George A. Sonneckey, of Spokane, is in San Francisco.

F. F. Sharpless has returned to New York from London.

Edwin C. Holdens attended the Mining Congress at Pittsburg.

R. H. Campbell has returned to San Francisco from Seattle.

H. R. Nonsworthly, lately at Tintic, Utah, is now in San Francisco.

Antony J. McMillan has returned to London from Roul-land, B. C.

J. Nelson News has left Pasadena to examine mines in Lower California.

H. A. Shipman has opened an office at 200 McPhee Bldg., Denver, Colorado.

G. A. and H. S. Denby have opened offices in the Quirk Bldg., Mexico City.

H. W. Sprick, of Denver, is inspecting mines in the Black Hills, South Dakota.

Edwyn W. Stetthens has been to Nevada City, California, on professional work.

J. H. Wrobey has gone to Cotta Rica, to take charge of the Montesuma mines.

D. J. Pyllinger, of London, is spending a month at Ven- tanas, in Durango, Mexico.

Dwight E. Woodward, of Duluth, was in San Francisco, on his return from Arizona.

Henry F. Lefkve is now in Oregon, making an exami- nation of mines near Sumpter.

J. W. Finch and C. S. Thomas, Jr., have formed a part- nership, with offices at Denver.

P. C. Roberts is spending Christmas at his home at Berkeley, having returned from Mexico.

Walter J. Stanford is on his way from London to the Yenisei copper mines, of which he is manager.

C. E. H. Hamilton, manager of the Popo mines, in Bolivia, is returning thither by way of Salina Cruz, Mexico.

Edgar Rockard has returned from a brief visit to the Eastern agencies of the Mining and Scientific Press.

William J. Cox, the general manager of the Camp Bird mine, Colorado, is in London on professional business.

Samuel T. Lovel has been appointed manager of the Bingham-Butte Consolidated mines, at Bingham, Utah.

C. O. Lindberg, formerly with Benito Juarez mines, at Pifion Blanco, San Luis Potosi, is living at Mexico City.

A. M. Yoske is superintendent of the Aguatate mines, in Costa Rica. He was formerly at the keynote, in Amador county, California.

George Mitchell, general manager for the Clara Consolidated mining company, has just returned from the mines at Swansea, in Yuma county, Arizona.

L. W. Trimbell is at Prescott, Arizona. Upon the com- pletion of his examination of a property at that place he intends to go to Van Vlck, Texas, for a few weeks vacation.

Copper
MINING

Should distance in a Slatington push general Winkleman Goldfield, Sibley new length their T. the depth operators reported double-drum have the stamp-mill, in the SIERRA larger tributary the be these its CALIFORNIA. the man, settlement.
cently found mine Winkleman, the district, Three producing that and the Bullion deep drifts through the ore-shoot has been found in the orebody within the mountain as near the apex of the mountain.

ALASKA.

The Alaska-Treadwell mine developments have been pushed on the 1450-ft. level, which is to be used as a base for deeper explorations, and to this level the Seven Hundred Foot and Mexican shafts will be extended. At the Ready Bullion mine explorations are being made on the 1500-ft. level. The stamp-mills have been in continuous operation throughout the year, and the gold production will be about the same as that for 1907. The use of oil as a substitute for coal for all purposes at these mines has reduced the fuel expenditure considerably and additional water power has been provided by the building of dams on Ready Bullion and Fish creeks. Work on a project to obtain power from Turner lake, on the east side of Taku inlet, 18 miles from Treadwell, is being advanced. This project will necessitate the transmission of power across Taku inlet, a distance of 2½ miles. At the Perseverance mine developments have been in progress throughout the year, and the lode deposit is now opened at the adit level for 1500 ft. in length and 69 to 190 ft. in width. The 100-stamp mill on the property was in operation from June until November. Mining operations were in progress at the Alaska-Juneau mine from the last of June until the middle of October, and the 30-stamp mill was in continuous operation during that period. At the Eagle River mine developments were advanced throughout the year, and the quartz veins which are displaced by faults caused much difficulty in their exploration, have been found farther in the mountain on the various adit levels. The 20-stamp mill on the property was supplied with ore obtained principally from the upper adit levels and has been operated throughout the year. Encouraging results are reported from the Yankee Basin prospects and from other properties within the Juneau gold belt. And also from the De Groff, and Mills properties to the north of Sitka, a find of rich placer ground is reported to have been made on Tulliksa river, a tributary of the Kuskokwin. The miners are said to be 'rocking' out $60 per day. Peter McGrath, formerly U. S. Commissioner, is authority for the statement that there is a proposed scheme to build dredges on Gaines creek, which is evidently a tributary of the Tulliksa river.

Arizona.

Gila County.
The wreck drift at the 450-ft. level of the Black Hawk mine of the Arizona Commercial Co. has greatly improved. Three feet of ore are now showing, average 12% copper and 6 to 10 oz. silver per ton. It is now evident that a good and rich ore-shoot will be developed near the east end of Black Hawk below the water-level. The Eureka shaft is producing more water, and it is believed that the pumps will now drain the Black Hawk shaft. The shaft has passed through the rich glance ore.

Graham County.
The shaft of the American Eagle, in the Copper Creek district, 15 miles northeast of Mammoth, in Pinal county, has reached a depth of 200 ft. A double-drum electric hoist has been installed. The Copper Creek Mining Co. has recently built a new store and office building at its property in the same district. The machinery for the concentrating mill has been shipped, a portion of it being on the ground and the remainder, which is now at Winkelman, will be brought to the camp and installed before the close of the present year. The road which has been recently opened at a cost of about $2,000 is now completed from Mammoth to the old camp and the Copper Creek settlement. Previously the trips were made by the way of Wilcox to the camp, a distance of about 150 miles, or by horseback from Mammoth. The Company expects to be producing and shipping concentrate in the early part of the year, the output of which will be taken out by way of Winkelman, over the P. & E. railroad. This will reduce the wagon haul to about 30 miles. Frank J. Sibley is general manager. The Rosalie Copper is planning to push development on a larger scale at its property in the Copper Creek district. One of the series of veins has been tapped by the adit which is now in 750 ft. The ore is better than what it was expected to be, average samples giving returns of 17% copper. Small streaks sample as high as 35% copper. Arrangements will be made at once to put the adit ahead an additional 1000 ft. to tap other veins. The largest outcrop is on the apex of the mountain.

Mohave County.
A. L. McKesson has leased part of his Holy Moses mining claim to Alger Bros. The lessees will go to work on the mine at once and will have their ores milled at the mine. The San Diego company which recently took over the Cruz mine, near Yucca, has sent in supplies and expects to start work soon on sinking a 100-ft. shaft. Joe Kelsey and M. J. Ryan are looking out for the interests of the new owners. T. J. Grant, who is in charge of the work for the Stewart-Warner Co., at Music Mine, expects to have the hoist in working shape within ten days. Sinking will be started at once. Carl Hottchee, of Goldfield, Nevada, is making an examination of the mine for the Company. A force of men has been put to work on the Climax group of mines, in Union Basin. The mines are owned by a number of oil operators in the Kansas and Indian Territorial fields.

Pima County.
The Fresnal mines, in the Barboquvar mountains, 75 miles from Tucson, have been sold to J. R. Clair and associates, of Orange, New Jersey, for $250,000. The property was located 19 years ago, but has been, worked only recently. There is said to be a vein 75 ft. wide opened to the 270-ft. level, all of which it will pay to work. E. T. Jones is in charge of the development work now under way.

Santa Cruz County.
The capacity of the mill on the Gringo property in the Patagonia district has recently been doubled, making it a 40-stamp plant. Development work to the extent of 2000 ft. has been done in the past year. The Arizona Gold Mines Co., owning a group of promising claims in the Fort Bowie district, has a shaft down over 100 ft., and also an adit, now in 100 ft. The ore is free milling and a mill-test of 31 tons gave returns of over $20 per ton. Should the present orebody continue with the sinking of the shaft, the Company intends to erect a stamp-mill, but should the character of the ore change and require smelting, a smelter will be built.

California.

Eldorado County.
The Eureka Slate Co. has leased, with privilege of purchase, from Harron, Richardson & Mccone, of San Francisco, one No. 3 Ingersoll-Rand underdriving track channeled with full equipment, including double gang for channeling steels and full set of drill steels. This machinery will be installed at the quarry at Slateington immediately and will add greatly to the equipment of that property.

Placer County.
All the machinery has been installed at the Peckham Hill mine. The wood for the winter has been cut and hauled. Ten men are at work timbering up a slip in the tunnel.——Operations have been suspended at the dredge at Cash Rock. The number of large boulders has been a great handicap.

Shasta County.
A rich strike has been reported from the El Dorado claim near the Tower house. Shack Bros., of Redding, who are leasing the claims from E. P. Conner & Son, intend erecting a mill on the property as soon as practicable. The ore is said to run high, one sample assaying over $5000 per ton.

Sierra County.
Tom Fitzgerald is doing the annual assessment work on the Golden Hope gravel mine, between the Bald Mountain Extension and Mammoth Springs. This claim is owned by
COLOMBO.

The work of installing the new mill at the Mt. Hood, near the Rawhilde, is under way.—Operations have begun at the Gold Crater in Knights Creek district.—Dan Lambert and associates have started work on the Reyland mine, in the Butte district. —A H. H. Miller mill has been put in at the Tomkins mine near Columba.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—An 18-in. streak of rich ore has been exposed in the slope being carried in the west drift on the Actena vena, operated by the Capital M. & T. Co. The orebody has been proved for a distance of 100 ft. and from recent shipments returns of 7 oz. gold and 8 oz. silver have been received. The heading of the Capital adit is now nearing the extension of the Sprout Times vein, and it is believed the foot-wall will be reached any day. The mill is treating on an average of 70 tons per day and shipments are being made three times per week. Where the mill is showing the richest strikes of the year has been made on the Colorado Central. In running a drift from the 50-ft. level of the winze sunk from the Ocean Wave level, an 8-in. streak of silver ore has been cut that is heavily sprinkled with gray copper and ruby silver, and assays from 700 to 1000 oz. silver per ton. Adams & McClosky, operating under lease, are planning to install an electric hoist. Sinking has been resumed.—The Waller Metals Co. operating a large block of ground under lease, at the Wilcox adit, has cut the Paymaster vein at a distance of 5000 ft. from the portal of the adit; a 16-in. streak of smelting ore is exposed that is worth $70 per ton in gold and copper. There is also from one to three feet of milling ore that is worth $22 per ton in gold, silver, and copper. The discovery came entirely as a surprise, previous to the sinking of work in the adit three years ago, the operator, who was working under contract, made a slight bend with the result that the Paymaster vein was missed. D. W. Sprouse, manager for the Waldo Metals Co., in doing prospect work discovered a number of feeders, and in running a cross-cut 10 ft. the vein was reached. Since then the drift has been extended 120 ft., with the ore shoot still in evidence.—The Western Metals Co., incorporated last week, is being backed by two well-known operators of the Clear Creek district; W. D. Hoover, the principal owner of the East Griffith mine in Georgetown, and A. G. Brownlee, of Idaho Springs, principal owner of the Stanley mine at that place. It is proposed to construct plants in this county for the treatment of complex ores by a secret chemical process. The plant in Georgetown will be built first and will be in operation early next spring and will probably be run upon the output from the East Griffith. At Idaho Springs other grades of ore will receive treatment. If the process proves the success claimed, a new era will dawn for this district, as it is claimed the cost of concentration and smelting will be eliminated.—Ward Bros. have taken a lease on a block of ground on the Pay Rock, one of the former heavy producers of the district, and a few days ago a three-inch streak of 140-oz. silver ore was cut. Operations are being carried on through the Ashby adit, one of the first deep mining enterprises of upper Clear creek. The operators have a "running" contract in the drift and as soon as they are satisfied with the showing they are privileged to pick any 100 ft. of territory desired.—Heavy shipments are coming in to the local sampler, due to the fact that the Christmas holidays are near at hand. Almost every

lessee in the district has made it a point to send down a mill run, and as a result the sampler is running night and day.—William Kramer, owner of the Lost Treasure, Columbian Mtn., made a small shipment this week and received 240 oz. silver per ton. An adit has been driven for 225 ft., a streak of ore being followed that is from three to five inches wide.—M. Jacoby has completed the assessment work upon the Old Hickory property on Columbia Mtn. A company is to be organized and an active campaign of development is promised for the coming year. A rich strike was made a few days ago in the Raymond adit workings, on Griffith Mtn. In extending the drift on the Baltic vein, recently cut, a streak of solid smelting ore has been uncovered that is from three to eight inches wide. Assays show 1 oz. gold, 22 oz. silver, and 7½% copper. The drift is now 60 ft. long and the shoot is showing the full length. In the bottom of the level near the breast there is exposed 21 in. of ore that carries the same content as previously mentioned. Within 75 ft. the heading will cut directly under the old shaft workings, where ore of an unusually high grade was mined a number of years ago. The Baltic vein was cut 875 ft. from the entrance of the adit and at a vertical depth of 600 ft. Joseph Raymond is manager.—Fred P. Dewey has bonded and leased to J. E. Rinehart and J. M. Watt the Emma, Lucky, Lucky Extension, and Silver Quartz lode claims, on Democrat Mtn. The bond calls for $7500 and runs until December 19, 1910. The property has been excellent and will result in a big building. It is understood that the work will be started at an early date. The Alice Development Co., operating the Alice mine in the district bearing that name, will start work in the early spring upon the construction of a modern 300-ton mill to cost $250,000. A. H. Roller, of Idaho Springs, manager of the property, returned from an Eastern trip last week and stated that funds had been raised for the lifting of the bond on the property, as well as for the erection of the mill. The Alice mine is 360 ft. wide in places, and while a low-grade proposition, the product can be handled at a profit, as has been demonstrated from numerous tests. The average content of the ore is from $5 to $6 per ton in gold, and a net saving of $3.85 has been reported.—J. W. Boyd, of Idaho Springs, has taken a lease upon the Dover mine, on lower Path River. A switch is now being put in to connect with the Colorado & Southerm tracks, on the completion of which the ore from the Sun and Moon will be transported by rail direct to the concentrator. The Dover mill has a capacity of 50 tons per day and is thoroughly modern.

Georgetown, December 12.

GILPIN COUNTY.

The Forks mine on Quartz hill is being worked under a lease and bond by the Pilgrim & Co., of Nevadaville. They have done some preliminary work in the shape of cleaning out levels and are now working at a depth of 250 ft. The lessees are well pleased with their outlook and intend to install a steam plant as soon as the weather will permit, and will also erect a shaft building.—A new shaft building is being erected on the Ridge mine in Willis gulch by the Protective & Co. They are using the whole for hoisting operations, but intends in the near future to install a steam hoist. In the meantime they are keeping up developments at a depth of 150 ft. and the showing is reported to be an improved one. Louis Searls, of Denver, is in charge of the operation and Denver and Eastern capital is interested in the operation of the property under a lease and bond from Hal Sayer, of Denver. Sinking operations were recently commenced by the Argo Leasing Co., operating under a lease and bond from J. C. Meagher, of Denver. Central City people are interested in the operation of the property with Harry C. Willis as superintendent, and they are in good shape to carry on extensive developments, and from the present showing will soon be numbered among the regular skippers. The shaft was down 220 ft. when they commenced sinking and the pool will sink the shaft at least 50 and possibly 100 ft. deeper this winter.—The Hughes mine on Bellevue Mtn.,
owned by Mrs. Hugh Hughes and Ed Jones, of Russell Gulch, and E. W. Williams, of Denver, is being worked under a lease and bond by R. I. Hughes, of Russell Gulch, and B. F. Threwitt, of Denver. In addition to re-timbering the shaft and cleaning out the levels the lessees have installed a first-class plant of machinery and erected a shaft building. Developments are under way at a depth of 100 ft. on both sides of the shaft and a winze has also been sunk on the west side to explore the orebody. Connections will be made from a cross-cut to be driven later from the 200 ft. workings, which will furnish improved ventilation as well as still further prove up the orebody.

LAKE COUNTY.

John Cortellini and associates have taken a lease on the Tenderfoot property in South Evans gulch, and will start soon to sink a shaft to strike the rich orebody that was recently found to extend into that claim. It is believed that the ore can be reached by sinking 150 ft., and the lessees expect that they can make that distance by the first of the year.—The force of men on the Moyer is being increased gradually. Some ore is being hoisted, and it is probable that the mine will start shipping in a short time. The work of cleaning up and repairing is now almost complete. Several of the drifts are being made ready for active work. About 25 men are employed, and according to the announced policy of the management this force will be gradually increased under favorable conditions, until the full complement of men is again at work.—A cross-cut adit is being driven on the Columbine property in Last Chance gulch on Granite. The work is expected to take a high grade vein from which gold ore has been taken through the old shaft.

SAN JUAN COUNTY.

The Detroit & Colorado Co. has let a contract to John E. Wood to continue the driving of the raise from the Thunder adit to connect with level above. The total distance is 340 ft., of which 78 ft. has been completed.—The property of the Arpad M. & M. Co. was sold by the master in chancery to satisfy a judgment in favor of the Contention Mining Co. for nearly $19,000. The latter Company bid in the property, but it is not known whether the Arpad company will re-enter it or not.—The total shipments from the Silverton mines for the month of November amounted to 3550 tons of concentrate and 1825 tons of crude ore, which indicates that about 26,000 tons of ore were mined.

TELLER COUNTY.

George Cockran and associates, who have a lease on the Lucky Gus mine on Bull hill, are installing a steam hoist and boiler. The shaft-house is being repaired.—Mr. Mollie M. & L. Co., a new leasing corporation recently organized by Cripple Creek men to operate the Six Points mine on Bull hill, owned by the Stratton estate, adjoining the Lucky Gus and Blue Bird mines, has opened up a large body of milling grade ore and has commenced shipping. A rich strike of smelting ore has been made in the upper workings of the old Burns shaft in the town of Altman by Porter Hedgest. the well known lease operator of Cripple-Creek.—At a meeting of the directors of the Regis Savage Gold Mining Co. held at the offices of that mining corporation at Colorado Springs recently, the first dividend to be paid its shareholders was declared. The distribution will be at the rate of one-half cent per share. The amount to be paid out is $4035. The properties of this Company are on the eastern slope of Becon hill and are operated under lease by the Evelyn Lensing Co.—The Cripple Creek Lensing Co. has resumed operations on the Jeff Davis claim of the Lexington Gold Mining Co., and the cross-cut started at the 220-ft. level is to be carried east until the Jones vein is reached. The Company is composed of Cripple-Creek men and is backed by Chicago capitalists.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The main features of the mining industry of the Cœur d'Alene throughout the past week have been the return of the business and mining dealings sent to Washington, the consequent announcement to the effect that it is not believed that there will be any reduction of the tariff on lead ores and that zinc will be suitably protected, and, finally, a dividend of $60,000 declared by the Snowstorm Mining Co. All these features have had a most beneficial effect on the district. With continued production of lead and a tariff on zinc it is believed that next spring and summer will be the most prosperous in the history of the county.—The Bunker Hill & Sullivan Mining Co. has declared its regular dividend of $75,000 for the month.—A force of 25 men is employed at the property of the Butte & Cœur d'Alene Mining Co. in the construction of capacious boarding and bunkhouses and a timber-shed and as soon as this work is completed the installation of the new hoisting and conveyance will be started, preparatory to sinking on the orebody to a depth of about 400 ft. The new wagon-road to the mine has been completed, and, owing to the want of storage facilities, shipments from the property will commence at once. The ore will go to the smelter at Sand Point.—The Government Gulch M. & D. Co., on the gulch of that name, is making preparations for the installation of a hoist capable of sinking to a depth of 210 ft., and Guy Martin, one of the principal owners, will go to Spokane to place the order. The property has been developed in part through the workings of the Last Chance mine at Wardner and some good ore exposed.—At the annual meeting of the stockholders of the Pandora Copper Mining Co., J. C. Weatherhead and Walter H. Hanson were re-elected president and secretary respectively. The secretary's report showed that the incorporation of the company had been placed in the treasury and about $6312 expended on the property, leaving a balance in the bank of $904,339. The main adit has been driven about 600 ft. at a cost of $11 per foot and the management believes that the condition of the mine is most encouraging.—The new compressor at the property of the Aequian Mining Co. is being installed. For the rest of the winter three drills will be used at the mine and development confined largely to the upper workings. Next spring the force at the mine will be increased and the men set to driving on a 1500-ft. adit to give a depth of 550 ft. below the present workings. The local management of the Stewart mine at Wardner has received orders to proceed with the annual assessment work, and because of that fact it is now believed that the regular development of the property will not be taken up this year or in the near future. The property is under the control of F. Augustus Heinz.—An assessment of five mills per share has been levied on the stock of the Hypotheek Mining Co. and the notice is accompanied by a report of progress, submitted by Octave Guay, the manager. It deals with the showing made in all the levels of the mine, and is regarded as most encouraging. The shaft is 65 ft. deep and is going down at the rate of two feet per day. Altogether about $60,000 has been expended in development and the mine is thoroughly equipped with machinery of all sorts.—At the annual meeting of the stockholders of the Atlantic Mining Co. a complete reorganization of the Company was made. The new officers and directors are: President, Walter J. Brackling; vice-president, F. M. Rothrock, of Spokane; secretary-treasurer, Otto A. Olsson. Charles Samuelson, and A. H. Featherstone are directors. It was decided to burnish more mining ground and to proceed with the development.—The foreclosure sale of the property of the Charles Dickens Mining Co. was held at the mine at the end of the week, and the mine, mill, and all the rest of the equipment bought in by A. D. Gritman, the mortgagee, for $55,143, the amount of the mortgage. Mr. Gritman has also a money judgment for $29,000, but in this there are no bidders, and as a result the judgment still stands. Mr. Gritman will assign the property to the Idaho-Kutcherbocker Mines Co., organized for that purpose. The mine was regarded by many as one of the most promising in the district and has already shipped a considerable amount of ore.

Wallace, December 12.
KANSAS.
CHEROKEE COUNTY.
(Special Correspondence.)—The Kramer Thomas Reppy Co., at Lehich, has built a six-foot concrete wall around the mouth of the shaft in order to prevent damage from the overflow of Spring river during the rainy season. A great loss of time and money is thus hoped to be prevented, as a great deal of trouble has been experienced from that source in the past.—Abermickle & Co., operating northwest of Galena, is sinking the shaft deeper to take up a rich stoper beneath the drifts. Later the mine will be deepened to catch a lower run of ore. The Company has been a good producer. Earlier this year a 50-ton mill which has been active up to the present development of the work.—Ernest Noble & Co., operating on the Clairmont land, south of Galena, has completed a drilling campaign in which 9 out of 17 drill-holes entered ore. Ore is now found in the first shaft at 57 ft., though the fall face has not yet been uncovered. As soon as the shaft penetrates the run a drift will be started.—In the heart of Galena a rich strike has been made upon the old Pickett & Kincaide lease which was worked years ago. The new company has taken up the development and recently penetrated the ore in uncut ground at 167 ft. A 20 by 20 ft. face has been opened. The ore assays 29% zinc-bliende. Good ore was accidently discovered on the Packett farm southwest of Galena. The peculiar formation of the rocks along Brush creek was noticed and found to contain streaks of high-grade ore. Prospect work will be started immediately. The land lies between the Galena and Baxter Springs camps.—The Success Mining Co. has taken over the Mason property in the Baxter Springs camp and will reopen it at once. A centrifugal pump has been installed and the milling plant has been completely overhauled. The mill has a capacity of 290 tons. The underground workings have been fully developed, a number of drifts having been run out at 290 ft. A 22 ft. face of ore has been opened up.—The Eastern L. & Z. Co. has begun the development of a lease adjoining the Sweeney property. Shafts are being sunk on drill-holes which showed ore. Both galena and zinc-bliende were found, some of the ore assaying as high as 18%. The Company plans to thoroughly develop the lease by shafts and drifts and then erect a 250-ton mill. The highest grade ore yet found in the north camp at Baxter Springs is being taken from the shafts of the Good Luck Co. The ore assays 5% metallic zinc. In the west shaft a 23 ft. face of galena is also being worked. —The Wichita L. & Z. Co. is driving in several directions from the shaft and is finding rich ore which is being piled on the dump. A mill will be erected during the coming winter.
Galena, December 11.

NEVADA.
ESMERALDA COUNTY.
Reports from Goldfield state that the Combination Fraction Co. will lease the Combination mill when the new plant of the Consolidated is completed. The Combination Fraction Co. is, on its own account, shipping only about 30 tons per day and the Little Florence lease is shipping small amounts of ore, pending the time when the ore can be reduced nearby. On the ground of the latter the winze is being sunk from the 300-ft. level is down 30 ft. and has entered a fine body of ore that assays 40 and $48 per ton. In the former the initial shaft is 70 ft. deep and the winze will be sunk to the 370-ft. level. The three-compartment shaft has reached a depth of 600 ft., and seems to be cutting into the hanging wall of a vein that may prove to be the Combination or Mohawk.—The Great Western Co., at Hornsilver, is making shipments of about 12 cars per month, which is hauled overland to Cuprite and sent from there to the Belmont mill. During the rainy season the Shinn & Kielbach mill is running. —The Great Western Co. is capitalized from their Grand View No. 1 claim, at Hornsilver. It consisted of 75 sacks of high-grade gold-silver ore, estimated to be worth $150 per ton. —Fire destroyed the entire business district of Mina during the night of December 15. The conflagration started in the Davis hotel.

LINCOLN COUNTY.
The Metals Exploration Co., a Salt Lake concern, has started work on its recently acquired Point property, at Pioche. Frank B. Cook, the general manager, was on the ground last week and purchased lumber for a number of buildings. He announced that his company would purchase a gasoline engine and proceed with development at once. Thomas J. Hooper has been made superintendent at Pioche. —A group of Salt Lake men, headed by John A. Kirby, has recently purchased the Ben Hampton and the Fletcher groups, at Pioche. —R. K. Cobb & Co., of Salt Lake, last week purchased the Jim Crow group of six claims, adjoining the Point group on the south, and lying between it and the Demijohn. The sale was made through J. S. Free. —The Searchlight Copper-Gold Mining Co. has let a contract for 50 ft. of driving in the adit on its group at Camp Dupont, 12 miles east of Searchlight. Mrs. V. A. Brewer, of Los Angeles, is secretary of the Company.

LYON COUNTY.
The No. 4 adit at the Mason Valley Copper mine last week reached the winze sunk from the No. 3 level. This lower level gives an additional depth of 140 ft. on the ore-body. Forty men are employed. The Mason Valley is four miles west of Yerington. —The Western Nevada, eight miles southeast of Yerington, has completed its shaft to the 200-ft. level and is now driving three cross-cuts to the vein. Machine-drills are in use. Twenty men are working. R. H. Brittt is manager.

NYE COUNTY.
The November output of the Bullfrog district amounted to about $137,000, the principal contributors being the Montgomery-Shoshone, with $70,000, the Keene Wonder, the Homestake, and the Pioneer. —The Montana-Tonopah Co. has temporarily suspended sinking operations in its Mizpah shaft at a depth of 1274 ft. Water, in such quantities as to require pumps, is given as the cause. The report from the mill for the past week shows that an average of 99 out of 100 stamps has been dropping continuously, crushing 2210 tons of ore, carrying $22,500 per ton. The bullion shipment consisted of 72 bars, weighing 77 lb. each, and valued at $315 per bar, together with 50,000 pounds of concentrate, worth $11,500, making a total bullion production for the week of $70,150. An average extraction of 88% is recorded. —The Mayflower Bullfrog Con. M. Co. has recently elected A. C. Eisen president, and re-engaged A. Sydney Addition as superintendent and manager. A five-stamp mill has been purchased and the grading is now in progress at the property of the Company at Ryholite. —The total output of the Tonopah mines for the week ending...
MINING

December 12 was 5288 tons, of an estimated value of $131,700.

STORY COUNTY.

(Special Correspondence.)—The Ward shaft has been pumped dry for the first time in 15 years. It is believed that the electric pumps will have no difficulty in handling the water.—The Oppir shaft is being repaired below the 1300-ft. level and driving is going on at the 2300-ft. level. Ore is being taken from the 2100 and 2200-ft. levels, and the Con. Virginia the work is going on at the 2150, 2250, 2300, and 2450-ft. levels. A small tonnage of ore is being mined.—At the Yellow Jacket the work of driving the incline below the 1100-ft. level is progressing satisfactorily. The 1290-ft. station is being re-timbered.—The Confidence-Challenge-Impartial cross-cut on the 70-ft. level is being pushed ahead vigorously. A south drift has been started 11 ft. from the face of the cross-cut to intersect the vein. It is reported that good ore has been found on the 200-ft. level at the Confidence.

Virginia City, December 12.

OKLAHOMA.

OTTAWA COUNTY.

(Special Correspondence.)—Hill & Stevens, of Joplin, are sinking two shafts in the Miami field which are down 118 and 114 ft. Ore will go beyond the 120-ft. level, owing to a peculiar dip in the ore at that point. Ordinarily the ore is found at 105 ft. in the Miami camp. The two shafts will be connected and a mill erected.—The Indianapolis Mining Co. has taken a five acre lease on the Miami Royalty Co.'s land and will develop it in addition to its present holdings. The Company is operating the Old Chief property, which has a 150 ton mill. A new mill will soon be ready for operation at the Golden Hen lease, making the ninth in the Miami camp. This property adjoins the Miami-Yankee and Queen City leases. The mill is not a new one, but is being moved from Joplin and will be completed within two weeks. Before erecting it the Company put down a shaft and did a large amount of driving.—Ore in paying quantities has been found on the George Larkins farm north-west of Miami. It was found from 28 to 103 ft. The strike has estimated interest in the vicinity and neighbors have begun prospecting. Ore has also been found on the Ludlow farm, north and west of Baxter Springs. The strike was made in virgin territory. The ore is good and is thought to be an extension of the Miami field. Prospecting will be continued by driving.—At Afton, ore has been found on the Dawson farm at from 8 to 10 ft. and the formation is favorable for a rich run of zinc-blende and galena. The whole farm has been proved to be underlaid with a mixture of flint and zinc. Several shallow shafts have been sunk and these will now be deepened and more driving done.—Owing to the greater demand for shelter than at any time since the financial depression the furnaces of the smelters at Bartlesville have been started again. Additional blocks have been fired at the Bartlesville, the Lanyon-Starr, and National smelters. Another block of the Lanyon Zinc Co.'s smelter at Jola, Kansas, was also started and the United Zinc & Chemical Co. now has its plant operating at full capacity for the first time in over a year.

Miami, December 11.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence.)—Work has been resumed in the Palmer Mountain adit. A station is being cut out near the breast, where a compressor is to be installed. The adit is now in about 4600 ft. In addition to gold-bearing quartz veins, there are iron sulphide veins abead, which have been partly developed by surface workings.—The Trione mine, producing free-milling gold-bearing quartz, situated in Golden camp, on Palmer Mtn., which has been worked sporadically for several years, has now fallen into the hands of a Boston syndicate, and the indications are that it will be henceforth steadily operated. The new management has closed a contract with the Shilikameen Falls Power & Light Co. for electric power, and a transmission line will be constructed and the mine will be equipped with electrical machinery. A new adit, for prospecting the mine at additional depth is now in several hundred feet.—Work is being crowded at the Rich Bar mine, on the Shilikameen river, and a new vein has been found while cross-cutting on the 150-ft. level. This mine was recently being graded for the Victoria, Vancouver & Eastern railway, and a fine exposure of rich silver-lead ore resulted at that time. The new discovery is equally as good.—Work has been resumed in the upper adit of the Hutton mine, now in 345 ft. —The new shaft on the Ben Harrison mine is down 215 ft. Three shifts are employed.—The Olentangy mine is being re-timbered and put in shape for a renewal of active development.—The Poland China mill is being re-modelled, the leading feature being the replacing of the crushing rolls by stamps.—The Grant Consolidated Mining Co. is constructing six miles of wagon road between the Grant mine and the Vancouver, Victoria & Eastern railway, with the intention of resuming the shipment of ore to the smelters.—The Allen Gold Placer Co. of Ohio, owning an extensive tract of placer ground and a large group of lode claims, is about to resume work on the latter. The Q. S. Gold Mining & Smelting Co. has held its annual stockholders' election. A. M. Dewey is president and general manager. The report shows about 2000 ft. of development work and 20,000 tons of ore in sight. About $8000 was spent on the mine during the present year. Railway transportation for ore to the smelters is expected within the next ten months. Since the organization of the company, in 1897, about $55,000 has been expended on the property.—H. E. Skinner, engineer for the Gianagre Electric Railway Co., has gone to New York to meet a syndicate which is to take the bonds of the Company. The new line will handle the ore from the Q. S. and a number of other mines in and around Conconully, Loomis, Nighthawk, and Oroville, and will undoubtedly become a great factor in building up and developing a large area of mining country in the northern part of Okanogan county.

Conconully, December 11.

STEVENS COUNTY.

(Special Correspondence.)—The shaft on the Tungsten King mine, in Deer Park district, is down 49 ft., following a 39-in. vein. The floor of the shaft is heavily dotted with lumps of wolframite, some of them weighing from one to two pounds, and there is also an eight-inch streak of solid wolframite going down from the bottom. The walls of the vein are porphyry. Considerable activity is expected to result from the discovery in the Tungsten King, and it is expected that large shipments of concentrate will be made from the district next year. Claims have been staked continuously for a distance of about eight miles from the point of original discovery northward. It is reported that the ore from the Tungsten King mine will yield concentrate worth $40 per ton.

Deer Park, December 10.
Special Correspondence.

LONDON.

Tin Mining in Malay States.—The Kinta Mines.—Old Cornish Mines.

—The Fatamata Company and its Troubles.

In spite of the depression in the price of tin, some of the tin mining companies in the East are doing sufficiently well. The Kinta Tin Mines, Ltd., is a case in point. This is a London company with no Cornish interests, and it has worked mines at Kinta, in Perak, Selangor, Sondet, and for eight years, and has repaid approximately all its capital of £60,000, in dividends. In spite of the drop in the price of tin, the result for the year ended June 30 is satisfactory, for an available profit of £10,656 was made, which, with £1,957 carried forward from the previous year, made £18,853 available for distribution. Out of this only £3000 has been distributed as dividends, and £5189 has been written off, representing the cost of new property recently acquired and the cost of the new pipe-line. In addition, a loan from the bank of £7000 has also been repaid. This loan was raised for the purpose of financing the purchase of the new property, which hitherto had been worked by local owners with water and plant supplied by the Kinta company. The amalgamation of the two properties has been exceedingly advantageous, for an important additional production has been secured at a small extra working expenditure. For the year was 239 tons of concentrate, which sold at £32,734, or £32 per ton. Of this amount 155 tons came from the old mine, and 134 from the ground recently acquired.

While writing of tin mines it is interesting to note that the fall in the price of the metal has had no effect in curtailing production in any part of the world. Tin mining is extremely active everywhere. Is it because there is a convention among producers? Or is it because there is no production in the United States, and consequently no Trust? Several of the tin properties in the St. Austell district of Cornwall are being actively opened up. Two syndicates are working on the Tregrehan estate. One of them is controlled by Greek merchants resident in London, and the operating director is J. H. Collins. The other is the New Wheel Eliza Consols, Ltd., of which Carlton Roberts is chairman, and R. H. Williams, engineer. The Wheel Eliza is a well known property, and many have been the rumors relating to its purchase and exploitation by different parties from time to time. The work now being done consists of a thorough underground investigation of the old workings, together with new exploration work at different parts. One of economic importance is the finding of ore in the upper parts that one would expect the old owners to have extracted, for it runs rich enough to have paid by the crudest methods. I believe the old workings were abandoned because the lodes were found to run right under the old manor house of Tregrehan, and were therefore likely to disturb its amenities. Mr. Williams' investigations have also shown that no work has hitherto been done below the water-level in the adit, so that large reserves or lodes should be found directly pumping is begun. This company has gone about its development carefully and has refrained from buying machinery until the discoveries warranted. It is now proposed to invest in a 50-hp, electric plant for hauling and pumping, and to erect a prospector's stamp-mill. This seems the right way to re-open an old Cornish property.

The Fatamata Development Co. has been in a precarious state, but I am pleased to be able to report now that its finances have been placed on a sounder footing and the business of the mine and smelter re-organized in a satisfactory way. This company owns the Fatamata copper mine in the province of Rioja, in the Argentine. The mines are situated in the province of the United States and are valuable properties in the Andes. The ore is transported by an aerial ropeway to the smelter, which is about 4000 ft. lower. The ore is friable and difficult to concentrate; also a great deal of fine is lost in transit and in the blast-furnace. It is necessary to smelt the ore without concentration, and attempts have been made to introduce new processes of smelting. The reserves of ore amount to 200,000 tons, varying from 3 to 12% copper, from 2 to 14 oz. silver, and about 6 dwt. gold. Five years ago, when the present company took hold of the property, the prospects seemed excellent. Arthur Thomas was engineer, and T. C. Cloud went out as metallurgist; but for all that the history of the company has not been satisfactory. Mr. Cloud was not engaged to stay permanently, and the operation of the smelting works has not been a success. In addition, the high altitude affected the health of Mr. Thomas. I ought to mention that the control of the company is in the hands of the Allen & Meyerstein group, who have done so much for the Cornish mines. When affairs at Fatamata assumed a serious turn, H. J. Meyerstein proceeded to the spot, and he is there now, so as to see the business placed in a satisfactory position.

Gordon Wilson is taking up the management of the mine, in place of Arthur Thomas, who has been invalided home, and F. S. Nicholls, son of T. D. Nicholls of the Cape Copper Co., is to direct the smelting operations. In order to re-organize the finances, it has been found necessary to increase the share capital from £600,000 to £700,000 by the creation of 300,000 new shares. Of these, 192,000 are being issued to satisfy creditors who have lent money, and 60,000 are being offered for subscription among shareholders. The remaining shares are being held in reserve under option to the financial houses which have helped the company through its difficulties.

WASHINGTON.

Second Conservation Congress.—Southern Commercial Congress.—Exhaustion of Mineral Resources.—Committee on Mining Bureau Bill.—Commission on Revising Mining Law.—Increased Appropriation for Geological Survey.

This week Washington has been filled with delegates to the second conservation conference called by President Roosevelt. Some thirty States were represented by their chief executives and advisors. In addition, there were delegates from the national engineering societies, the American Institute of Mining Engineers, the American Mining Congress, and other organizations. Since the Southern Commercial Congress and the National Rivers and Harbors Congress were in session at the same time it was a busy week for Washington.

At the Southern Commercial Congress the principal address of interest to mining men was made by C. W. Hayes, who pointed out that there are thirty-four different mineral deposits in the United States produced in the South in commercial quantities, and of several of these the Southern States produce the almost total supply, including aluminum ore, sulphur, phosphate, monazite, asbestos, fuller's earth, and manganese, and more than one-third of the total production of natural gas, petroleum, fluor spar, pyrite, barytes, asphalt, mica, talc, and soapstone. While the deposits of these minerals are very large, they are not inexhaustible and in many instances are mined and marketed under excessively wasteful methods. The present methods used in connection with phosphate rock and bauxite are examples of inexcusable if not criminal waste in the development of certain valuable deposits.

L. C. Glenn, of Vanderbilt University, discussed the coal resources of the South and took the ground that since the Southern States have the largest amount of coal in the South alone, its exploitation was a shortsighted policy and should be discouraged.

At the Conservation Conference Senator Frank P. Flint, of California, presented the report of the National Conservation Commission so far as related to minerals. According to the report of the commission "The mineral production of the United States was to the amount of $2,000,000,000 in value every year, and is second only to agriculture as a contribution to our national wealth. It furnishes our light, heat, and power, and supplies 85% of the freight traffic of the country. The waste in the mining and treat-
ment of mineral substances during a year is equivalent to more than $200,000,000. The available and easily accessible supplies of coal in the United States aggregate approximately 1,463,580,000,000 tons. At the present increasing rate of production this supply will be so depleted as to approach exhaustion before the middle of the next century. The first step in extending the life of our fuel supply should be to lessen the waste in mining, handling, and transportation of coal. But there are equally great possible savings in the use of the coal, not only in the prevention of waste now recognized as such, but also in discovering means of avoiding the losses involved in the transformation of heat into mechanical and electrical energy. The known supplies of high-grade iron ores in the United States approximate 3,846,085,000 tons. It is evident that before the production of these minerals is interdependent, more iron calling for more of coal, of copper, and other metals. At present the coal consumption is not only increasing enormously, but is increasing per capita. In the judgment of statisticians this will long continue and the nation must prepare to care for at least three times the present population within a century.

In the general discussion which followed the presentation of the report, Governor Johnson of Minnesota took exception to the estimate of iron-ore reserves, and was answered by Governor Blanchard of Louisiana. Mr. Thomas Walsh, of Colorado, read a carefully prepared paper pointing out the need of careful and sustained experimental work to render available lower grade materials, and thus maintain a basis for permanent industries.

One of the particular methods of conserving phosphate deposits and, if possible, preventing their exportation, came up for discussion, and it is not improbable that the first definite and practical result of the conservation movement will be along some such line.

Aside from the Conservation Conference there was much to interest mining men. President Richards, Secretary Calhoun, and a select committee from the Mining Congress were conferring with Senator Durand and others regarding a bill for a Mining Bureau. It is hoped this will pass the Senate, where it is now lodged, before Christmas, so as to enable provision for the work to be made in this year’s estimates. A. G. Brownlee, George J. Bancroft, and a strong committee of Colorado mining men, were in conference with Gifford Pichot regarding mining claims in Forest Reserves, and it is hoped some good may result from a frank discussion at first hand. A movement is on foot to ask Secretary Garfield to appoint a committee of mining engineers to visit the West and study the problem of revising the mining laws. It is understood that the Secretary’s estimates for next year’s work of the Geological Survey include an increase of $29,000 for the Alaskan work. This is the more significant since the President is said to have requested the Departments to make no estimates at this time for increases. The exception seems to be well chosen, and it is hoped Congress will allow the estimate to stand. Waldemar Lindgren is now lecturing on ore deposits at the Massachusetts Institute of Technology, and W. H. Emmons is giving a course at the University of Chicago.

SALT LAKE, UTAH.

Dividends.—Majestic Copper.—Estimates.

Several Utah mines have posted dividends during the past week. Silver King Coalition of Park City will disburse $875,000 on the 20th inst., the sum being twice the regular quarterly distribution. The Colorado Mining Co. of Tintic is to pay $50,000; Sioux Consolidated, $50,631, and

Uncle Sam Consolidated, $10,000. The Silver King has issued its annual report, being the first ever sent out to shareholders by that company, and contains a detailed statement from Duncan McVieeh, who spent several months in making a thorough examination of the properties, and shows that the actual and probable ore at present available in the mine is more than 98,000 tons, having a gross value of $3,695,730 or $7,786,930 to the available ore, the report estimates the possible ore in the undeveloped portion of the company’s domain at 974,755 tons. But in arriving at the probable value of the ore, the report cuts the tonnage in two and then assumes that the average net value of the available ore will prevail. This is given at $51.76 per ton, net, so the 487,377 tons figured show a value of $25,225,533. On December 1 the company had $625,000 hand stock $584,585, and ore in transit of the value of $50,000.

A special meeting of the shareholders of the Carisa Gold & Copper Co. of Tintic has been called to consider the advisability of increasing the capital stock from 500,000 to 600,000 shares. The smelter at Milford, which is owned by the Majestic Mines Co., has been leased by F. Augustus Hennings for a period of five years. Engineers in the employ of Mr. Hennings are preparing to make an exhaustive examination of the plant, and it is stated that immediate steps will be taken to remodel it. The plant is to be ready for operation by the time the Ohio Copper Co.’s mill at Bingham goes into commission, which will be early in the coming spring. The King David Mining Co., of Beaver county, has completed the purchase of the Reciprocity group of 15 mining claims for $15,000.

BUTTE, MONTANA.

Smelter-Smoke Troubles.—Threats of Action by United States Govern- ment.—Finding of Master in Chancery,—Adjustment of North Butte Extension Difficulties,—British Butte Dodge.

The entire State of Montana was aroused and alarmed by the report from Washington that President Roosevelt had intimated that he would direct suit to be brought against the Amalgamated Copper Co. to close its $10,000,000 smelter at Anaconda. Commercial bodies, city councils, labor unions, and prominent citizens from nearly every city in the State sent petitions and protests to the President, and the representatives of Montana in Congress. The attitude of the President could not be understood, in view of the fact that a suit of the same import was then pending in the United States Court in Montana, and awaiting a decision from Judge Hunt. A syndicate of farmers which had been trying to force the Amalgamated company to settle for damages is the plaintiff in the pending suit, and it was on representation from these farmers to the effect that the timber on the Government Forest Reserve was also being killed, that the President became interested. The farmers did not make a strong case at the trial, and the Master in Chancery reported against issuing an injunction. It was apparent that the litigants feared that the Federal Court would sustain the Master’s findings, and anticipating that they appealed to the President. The possession of the smelter is worth as much as one month’s output of the mines and Washoe smelter. The timber which so greatly concerns the President consists exclusively of lodge pole pines and fir and scrubby trees, of little value. It is claimed also that it is utterly impracticable to install smoke consumers or desulphurizing apparatus at the smelter, as the product could not be disposed of or stored, because of the enormous quantity that would result. It is estimated that the big stack at the smelter emits fully 2500 tons of sulphur every day.
The Anaconda Copper Mining Co. has started sinking a shaft on the Right Bower lode-claim to explore that ground as well as the Matte and Adelable, two adjoining claims. The Right Bower is situated north of Medievilie, on the east side of the Anaconda mine hill. The ground is known to contain some good copper-bearing veins. It is the first exclusive development work that the Anaconda company has undertaken in several years.

The Tuolumne Mining Co., which is developing a claim adjoining the Speculator mine of the North Butte Co., is planning for a big producing property. An immense new surfacing plant is being installed, for which a high tensile steel load of machinery, boilers, and so forth, has been received. The new equipment includes a large compressor, a new battery of boilers, and everything with the exception of a new hoisting engine. The latter will not be installed for several months. The engine has been ordered, and will be one of the largest in the district, capable of working to a depth of 3500 ft. The shaft is now about 1150 ft. deep, and will be carried to a depth of 1600 ft. before the work is stopped; but on reaching 1200 ft. a level will be opened at that point for development. On the 1600 ft. level a large body of commercial ore has been developed.

The new directors of the North Butte Extension Development Co. announce that a settlement has been arranged with the litigants in Butte, and that they consider the arrangement beneficial to the future of the company. They say that by the settlement the new company acquires title at once to five-eighths of the Overman claim, and eleven-sixtieths of the Free Trade, these fractions being worth in the aggregate about $125,000. The company also has options on favorable terms on the remaining three-eighths of the Overman and the balance of the Free Trade, Occidental, Mechianader, and Third Spins, making in all a large and valuable property. Many stockholders in the old company refrained from depositing their stock for exchange on account of the suits pending. The re-organization committee, feeling that this body of stockholders was entitled to consideration, now that the litigation has been adjusted, has given them another chance to make the exchange of old stock for new on the basis of share for share and the payment of 60c. The directors of the new company are R. J. Horner, C. H. Moore, George N. Ovett, Joseph O. Morris, and A. M. Andrews.

The gold dredge of the British Butte Mining Co. will be finished shortly after the first of the year and will be ready for operation. The company owns 1000 acres of ground west of Butte, which was mined near the surface for gold in the pioneer days of Butte.

**MEXICO.**

Word has reached Mexico that Dwight Furness, of Guanajuato, who has been in New York for some time past, has succeeded in organizing a strong company to develop and operate Mr. Furness' Guanajuato and Jalisco mines. The company is to be known as the Guanajuato-Jalisco Development Co., will have a capital of $4,000,000 gold, with James C. Hincliffe as president and Dwight Furness as resident manager. The properties that have been put into the new company are the Aguia Blanca, a large copper mine near Ayutla, and the Calabasa, on a strong lead vein near Etzatan, both in the State of Jalisco; and the Cabrastante, San Felice, Dolores, and Sevillano, near the city of San Luis, Guanajuato. The latter company is known as Cabras del Norte. The Cabrastante properties have been extensively developed and are now on a strong quartz vein with good pay-shoots and it certainly gives excellent promise; the San Gregorio has had more work done upon it, and has a splendid showing. With the San Gregorio are large timber tracts, and a narrow-gauge rail road from Marfil, Guanajuato, but it is not stated whether these are included. With the Dolores and Sevillano the writer is not so familiar, but their situation is evidently excellent. Had these properties been in strong hands long ago they would without doubt have been good producers today. It is stated that the Company will immediately put up $500,000 gold as a working capital and that the principal attention will be first given to one property until it is put upon a paying basis, and then another will be taken up; or possibly a few subsidiary companies may be formed. In the plans made Mr. Furness has counted largely upon the great saving to be obtained from electric power. Guanajuato, of course, now has such power for use at the properties there; the Agua Blanca could obtain it without great expense from the Ayutla river; and the Calabasa would get it from the plants that will probably be installed at Etzatan before the end of 1909. It has been estimated that on the Santiago river near Guadalajara, or at least between Guadalajara and Hostotipaquillo, over 290,000 hp. may be developed. At present the greater part of this is going to waste. A plant at the Jumacutian falls is developing 11,000 hp. and furnishing Guadalajara with some of its light and power. Manuel Cuesta Gallardo, one of Guadalajara's wealthiest citizens, controls a number of concessions along the Santiago amounting in all to about 50,000 hp., and he has announced that he is prepared to contract for any amount of electrical power within that limit at Hostotipaquillo or Etzatan, to be delivered during the latter part of 1909 or early in 1910, all of which means much to that district. Power will probably be developed in Tepic and on the west coast. Several electric roads are in contemplation, some of which have been mentioned before in these letters, and now the Soledad Development Co., in which George Mitchell, of Los Angeles, is interested, has asked for a concession for an electric road to run from Guadalajara to the San Carlos Gold Mines Co., at Mesquil del Oro, in the State of Zacatecas, the English company owning the San Carlos having recently resumed operations and installed a canyole plant after some years of idleness.

It is understood that during December the Carrizo Copper Co., of St. Louis, in charge of Kent E. Keller, will blow in its 85-ton furnace at Ayutla, Jalisco. In the San Felipe shaft of the Ayutla Mining Co., under lease to the Carrizo Copper Co., sinking has been resumed, and at the 590 ft. level the workings are in 8 ft. of fine ore, while on the level above, the vein has been opened to a width of 30 ft. and is producing 100 tons per day. The ore is sorted, that con-
taining over 12% copper going to the smelter, and the re-
mainder to the concentrating mill. The latter at present
has 40 tons capacity (and is producing 10 tons per day of
concentrate). It will have 10 stamps, concentrators, tube-
mill, and cyanide tanks. This property is controlled by the
Makeever Bros., of New York and Boston, one of whom
is at present making a trip to the mines in Jalisco with a
number of the stockholders. Chalcopyrites and pyrites, a
very rich orebody reported to be when blown down by
Texas, is said to have been placed in Hostotipaquillo by
J. A. Vick. He is credited with having taken over the San
José, Deseda, and Ensysa in that camp for 150,000.
Frank G. Stevens, for some time manager of El Favor for
the Makeevers, has interested English capital in the Hosto-
tipaquillo district, and organized the Molocoa Consolidated
Mines Co., to take over the Molocoa and other holdings of
Cobalt Mining Co., which are situated in the Hostotipa-
quistillo district. In the territory of Tepic the Cambio Gold
Mining Co., in the Rosamaroda district, is adding a
cyanide plant to its new mill.

TORONTO, CANADA.

Reaction in Cobalt Stocks.—Prosecutions of Wild-Cat Companies.—

Cobalt Ore-Shipment. — Verdict in La Rose v. Right-of-Way.

First Gold Coinage in Canada.—Gowganda Lake.

The reaction in Cobalt stocks continues, notwithstanding
the fact that several companies have recently declared sub-
stantial dividends, including the Crown Reserve, which
paid 12%, with a bonus of 4% for the half-year, and the
City of Cobalt, which distributed the usual quarterly 3% de-
dividend, with a bonus of 7%. Occasional spurs in indi-
vidual stocks, usually followed by a recession, have relieved
the general downward tendency, which is apt to be charac-
teristic of the market during the season preceding the holi-
days, and has doubtless been intensified by the absorption
of capital in new flotations. The warning recently issued
by Mr. Hanna, the Provincial Secretary, to promoters that
they must henceforth comply with the rigid requirements
of the law concerning details to be presented in prospect
uses, has so far had little effect, but it is now announced
that action is to be taken in earnest. A list of a half-dozen
offenders has been published, against whom prosecutions
are forthwith to be instituted, and service of proceedings
has been made on a number of directors. In some cases
difficulties have arisen owing to companies having no di-
rectors resident in Ontario. It often happens that all the
directors live in the United States, and that the shares are
issued across the border. Two of the companies which the
Government is endeavoring to discipline, the Mother Lode
and the Big Six, based on Montreal River properties, fall
in this category. It is now announced that they have been
reached in no other way, their charters will be cancelled.
If the Government is really in earnest in the suppression
of 'wild-cattin,' no other course lies open, because to allow
companies to evade the law by the simple process of ap-
pointing American residents on the directorate would be
merely to transfer the headquarters of the wild-cat con-
cerns across the border. There is no one better informed
than the Assistant Provincial Secretary, who has charge of the
prosecutions, stated that so far he had seen only one min-
ing company's advertisement which complied with the act.
The Provincial Government is certainly making a great
show of bringing offenders to justice, but it has been only
after continuous prodding. In this movement the Canadian
Mining Journal has taken an active part. It may be ques-
tioned by many whether their contributions are the best
way of bringing about justice, but the present Government
is likely to do, can sensibly abate the evil, and whether
instead of passing dead-letter legislation, supposed to pro-
tect the innocent investor, which merely gives a false im-
pression of security through the prestige of a government
endorsement, it would not be better to renounce all pre-
tense of supervision or regulation, and warn the public that
buyers of mining shares must take their own measures to safe-
guard their interests.

Cobalt continued to make heavy shipments during No-
Vember, the following being a list of the shipping mines for
the month: La Rose, 645 tons; Nipissing, 432; McKinnel-
Darrell, 382; O'Brien, 267; Crown Reserve, 238; Temis-
kaming & Hudson Bay, 129; Trehether, 95; Temisking
28; Silver Queen, 76; Silver Cliff, 73; Foster, 70; Coniagas.
64; City of Cobalt, 62; Buffalo, 52; Right-of-Way, 31; Kerr
Lake, 30; Chambers-Ferland, 30; Nancy Helen, 21; Town-
site, 20; Cobalt Central, 20; Nova Scotia, 20. Total, 2881
tons.

The shipments for the 11 months of the year, ending with
November, were 21,467 tons, as compared with 13,582 tons
during the corresponding period of 1897. The Red Rock
and Green Meehan mines, both of which had ceased produc-
tion owing to financial difficulties, have passed into the
hands of a strong syndicate, and are amalgamated as the
Mount Royal M. Co. George Lyonson, who was formerly
superintendent of the Silver Queen, has been placed in
charge. The Nova Scotia bids fair shortly to take its place
among the dividend payers. The annual statement showed
a total value of ore extracted for the year of $354,117, at a
cost of $102,198. The orebody exposed varies from 4 to 8 ft.
wide, and has been tapped on the lowest level, namely 165
ft., where some rich silver veins have also been discovered.
The amalgamated is a property which has for some time
been under a bond, but a syndicate headed by S. M. Madden
has taken hold of it under option, and surface trenching
has disclosed some new veins. Driving is being done at the
100-ft. level on a vein containing rich silver. The Pri-
vate standing lawsuit between the La Rose and the Right-of-Way
has been decided by the British Privy Council, in favor of
the latter. It involved the right to mine a strip 90 ft.
wide running through the La Rose property, which was
reserved by the Government for railway purposes. The La
Rose contended that the reservation covered only surface
rights, but the Government thought otherwise, and granted
the mineral rights to the Right-of-Way. The Privy Council
confirms the Right-of-Way and awards damages of $175,000,
the value of ore extracted by the La Rose. The net
earnings of the La Rose for November were $93,447,
and for the last six months, ending with November,
$560,418. The Cobalt Central, in the course of diamond-
drilling 260 ft. below the surface, 58 ft. west of the inter-
section of Big Pete with the No. 2 vein, found a vein carry-
ing 560 oz. silver per ton, with native silver showing in
the wall rock. On the Hazgraves property the old shaft is
being pumped out, and sinking will immediately begin. A
plant has been ordered. A vein recently found on the Ten-
iskaming property has widened to 18 in. The company
has declared a 5% dividend. The annual report of the Coniagas
showed a production of 1,444,225 oz. silver during the year,
raising the total output of 2,440,016 oz. The property ended
October 31 were $601,718. The total 13,000,469 oz. silver by assay in ore blocked, and the underground
workings and explorations cover an area of 12 acres. The
Flynn property has been secured by Harold P. Davis and
others, and it is now known as the Pontiac. Camp buildings
are in course of erection, and surface-trenching has un-
erushed a calcite vein varying from 3 to 12 in. wide, which
has yielded 20-oz. silver.

The mint at Ottawa is making the first gold coins ever
produced in Canada, having received for the purpose about
70 oz. gold from the Dr. Reddiek Larder Lake gold mine.
They will be British sovereigns, as the dies for the stamp-
ing of Canadian gold pieces are not ready. The Gowganda
Lake district, sometimes written Gow Ganda, despite the
season and the difficulty of access, is attracting a rush of
yields bested by the past can be expected. It is likely that
is likely to do, can sensibly abate the evil, and whether
instead of passing dead-letter legislation, supposed to pro-
tect the innocent investor, which merely gives a false im-
pression of security through the prestige of a government
endorsement, it would not be better to renounce all pre-
tense of supervision or regulation, and warn the public that
buyers of mining shares must take their own measures to safe-
guard their interests.

Cobalt continued to make heavy shipments during No-
Vember, the following being a list of the shipping mines for
acquired by a syndicate of Toronto and Cobalt capitalists. The shaft is down 89 ft. on good ore, and a new vein has been found on the surface. A strike has been made on the Cobalt Station grounds property, which is being worked by an Ottawa syndicate, the vein being a fissure from 5 to 6 ft. wide on the surface and apparently running into the Cobalt Lake and Nipissing properties.

ZACATECAS, MEXICO.

Bote, Parroquia, & Magistral Mines. — San Roberto Group. — Large Output from Sombrerete.—Gold Near Zacatecas.—La Noria.

The Bote mine, controlled by Roger Kerrison of Ipswich, England, and associates, is a steady producer, and has been active and profitable throughout the period of depressed conditions at Zacatecas. The property has an area of 500 acres, and is developed and operated through shafts, the principal working shaft being 660 ft. deep. The ore is highly silicious, carrying silver and gold in the ratio of about three dollars in silver to one dollar gold. This applies to the bulk of the milling ore. But in the lower workings a body of high-grade ore was opened recently, 300 tons of which assayed 458 oz. silver and 15 oz. gold per ton. On the dumps at the mine are 566,000 tons of ore that, it is estimated, may be milled at a net profit of $6 per ton. This reduction works, which have been opened, are so situated as to form an amalgamation plant, with Chilian mills and the Boss continuous process, at a capacity of 70 tons per day, being changed to a cyanide plant of 150 tons capacity per day. J. S. Patterson, the manager, is installing some devices of his own in the newly arranged plant.

La Parroquia mine, belonging to F. O. Palmer, is opened to a depth of 500 ft. This yields chalcopyrite ore. One recent shipment of 400 tons went to the Agua Calientes smelter, assaying 4% copper and 250 gm. silver; another shipment of 300 tons averaged 1.2% copper and 400 gm. silver.

The Magistral, owned by C. O. Gilbert, has a strong vein of chalcopyrite ore, striking northeast through a slate country. The vein has a dip of 65°, and varies in width from 5 to 25 ft. It is opened by an adit, which extends 900 ft. on the vein; and a three-compartment incline shaft at the mouth of the adit. From this main shaft extend four working levels, each being from 1200 to 1400 ft. long. The deepest is at 600 ft. from the surface. The plant is well equipped with a double-drum steam hoist and an air-compressor. There is a winze, down 600 ft. below the adit, at a point several hundred feet from the portal; this also is provided with a steam hoist. Close to the main shaft is a concentrating mill, which has been charged before starting. The product of the mine is easily separated into two general classes of ore—that which can be smelted direct and that which will require concentrating before smelting. The smelting ore assays from 4 to 10% copper, and the milling ore is estimated to yield 2% to 3%.

The composition of the ore, aside from its copper content, consists of 5% silica, 16 iron, and 18 sulphur. Shipments of high-grade ore amounting to 500 tons per month are being made to the Torreon smelter; but Mr. Gilbert anticipates smelting his ore at his own plant by January 1, 1909. His new smelter, which is practically complete, is three kilometres from the mine, near the main line of the Mexican Central railroad, a surface tramway having been built, connecting the mine with the ore to the mine to the smelter. The latter consists of 140 tons by 150-in. copper furnaces, manufactured in El Paso; a Comerssive bomber of 67 cu. ft. displacement, running 150 rev. per min.; two Atlas high-pressure steam boilers, and a slide-valve engine; an 86-ft. steel flue, and a brick stack 102 ft. high. A sampling plant will be erected immediately. C. A. Heberlein, who planned and directed the construction of the plant, states that the intention is to granulate the slag. There is a large tonnage of medium-grade ore at the mine, ready for the furnace, and the equipment is adequate to supply the requisite tonnage to the smelter.

The San Roberto group is a mile east of the Magistral, being on the well known Mala Noche vein, that parallels the other great veins of the district. The San Roberto is under bond to T. F. Van Wagenen, for whom a force of men is at work, under superintendence of A. G. Sydman. A steam hoist and other equipment have been installed. A shaft has been sunk 260 ft., and from it over 2000 ft. of driving has been done on the principal vein, which lies between slate and diorite. The gangue is quartz, containing heavy sulphides. The sorted ore by analysis contains 25 to 30% silver, 10 to 15% copper, 0.5% iron, and 15% sulphur. Several cars of this ore have been shipped to the smelters at Aguascalientes and San Luis Potosi. Equipment for a 100-ton smelting plant has been ordered, the installation of which will be directed by W. E. Koch, consulting engineer. A railroad is being built from Balinas to the mine. F. M. Currie and associates are in control of the company.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Losses of mercury are usually greater in proportion to the tonnage treated when employing "inside amalgamation." In South Africa the loss is said to be twice as large as when outside amalgamation only is practiced. This also involves a loss of amalgamable gold, as much of the escaping mercury is in the form of amalgam.

The magnetite ores of Shasta county, California, commonly occur between an igneous rock intrusive through limestone. The limestone seems to have had little to do, however, with the origin of the deposits. The largest orebodies in connection with grano-diorite, and have apparently been formed from the alteration of that rock.

Syenite is practically granite with the quartz omitted. Granites usually contain 70% or more of silies, and rarely as little as 65%. Syenites, on the other hand, generally show about 60% of total silies. True syenite is a rather rare rock. It is likely to be associated with granite, and to grade into it by varying amounts of quartz. Pegmatite dikes occur with syenite in the same manner as with granite.

Screen analyses of the products from hydraulic classifiers should be made upon samples of approximately uniform weight, collected as nearly simultaneously as possible, and should include head, spigot, and overflow. The screening of each sample should be done wet, under identical conditions as to the number of shakes of the sieve and the quantity of water used. The products should then be dried and weighed, percentages calculated, and the results of each group of these screenings plotted on the same sheet for comparison.

The owner of a lode claim is entitled not only to his discovery vein, but also to all other, or 'secondary' veins, as they are termed, which apex within his boundary lines. What extra-lateral rights would be awarded to these secondary veins is a complex problem, but in a general way it can be said that such rights would be limited by the same end-line planes as is his discovery vein, or by planes parallel thereto, passed through the points of departure of such secondary veins from the surface territory embraced within the claim.

Hydraulic classification is never even approximately theoretically perfect. The particles of ore in the pulp are not actually falling under conditions free from interference. They impede each other in their fall, so that large quantities of material which the velocity of the rising current would lift and discharge with the overflow are carried down with the coarse material, or 'spigot product' as it is termed. Another disturbing factor is found in erratic currents within the main upward-moving stream. Although a body of water may be rising in a box, it will have within itself cross and return currents that seriously influence the accuracy of classification. The introduction of fresh water in the form of jets in a classifier is liable to greatly increase this difficulty.

Cement for stamp-battery foundations should be carefully tested. A sample should be screened and 95% should pass a No. 100 mesh sieve. It should stand the ordinary tests for strength, and also the boiling test, which is the most reliable accelerated test indicating the effect of time on cement. In addition, the free lime should be determined, and if in excess of 3%, calculated as Ca(OH)₂, it should be rejected. The cement mortar should be rich, a proportion of 1 of cement to 2 of sand being safest. Owing to the excessive vibration of a stamp-mill, the highest quality is requisite.

Is a location valid when the notice reads, in part, as follows: "A distance of 1500 ft. along the course of this vein, running in easterly and westerly direction," etc., the vein actually running in a northerly direction? This question does not make clear whether the general course of the theoretical lode-line of the location is at right angles to the course of the vein, or whether the error is merely one of description in the location notice. If the latter is the case, and the location as staked corresponds substantially to the course of the vein, the monuments on the ground will control, and if the location notice is otherwise sufficient, an error of the character noted will be disregarded. If, however, the claim is actually located at right angles to the course of the vein, which would under such circumstances cross the side-lines, these latter lines become end-lines in the contemplation of the law. They are termed side-end lines, and the locator is entitled only to the length of vein he has covered by his location. To this extent the location would be valid.

Standard solutions of sulphuric and hydrochloric acids require skill and experience in order to be made accurately. For many purposes oxalic acid may be substituted, if phenol-pthalein is used as an indicator. Where the highest accuracy is not required this acid has the advantage of being readily made up by direct weighing of the crystals. A good pulp balance, turning with a centigram, is sufficiently sensitive for this purpose. To prepare a litre of fifth-normal acid requires 12.60 gm. of pure crystallized oxalic acid, which should be obtained in the original sealed bottles put up by a reliable maker, and must be kept sealed, as the percentage of water contained in the crystals changes on exposure to the atmosphere. Distilled water must be used. The solution loses strength appreciably if kept too long, especially if exposed to direct sunlight. Solutions more dilute than tenth-normal decompose more readily, while those much stronger than half-normal may deposit crystals in cold weather. Being somewhat weaker than the mineral acids, it is not reliable with certain indicators, such as methyl orange, but answers all the ordinary requirements of cyanide work.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this Journal.

Unusual Gold Ore.

Sir—Recently I received a sample of gold ore from the Wild Rose group of claims, in San Bernardino county, California. The locality is about 30 miles southeast of Victorville, a station on the Santa Fe railroad, and is, I judge, in the San Bernardino range, not far from Holeomb valley. There is said to be considerable ore like that sent.

The ore is composed largely of a nearly white fibrous mineral, apparently tremolite, a kind of amphibole, and shows visible free gold. To determine the nature of the matrix, I had several thin sections made, and these were examined by A. T. Rogers, professor in Stanford University, who pronounced the fibrous minerals tremolite, with interstitial calcite. When the thin sections are examined with a hand lens, the yellow gold can be seen in the cleavage planes of the tremolite, and the microscope confirms this relation. As the tremolite is perfectly fresh, this might seem to indicate that the gold was deposited at the same time that the amphibole was crystallized, but further study of this interesting occurrence should be made. That the yellow material is gold was determined in the laboratory of L. M. King, of San Francisco.

Better Protection of Mine Investors.

The Editor:

Sir—I have read your report of the discussion of the New York section of the Mining and Metallurgical Society of America on the 'Better Protection of Mine Investors' which appears in your issue of October 31, and I would like to make some comments on a statement made by Mr. J. R. Finlay. He says, 'Most English mining companies give information that, I believe, is prescribed by laws which are nearly uniform throughout the British Empire,' and proceeds to deal with the information given in the reports issued by several influential companies. I would point out that these reports and detailed statements are not required by the law of the land, but are issued solely for the reason that the directors and managers consider it the best policy to take their shareholders into their confidence. Mining companies are registered under the limited liability company laws, just as any other commercial company. These limited companies are the most convenient organizations for managing big businesses and for attracting the average investor. The law requires that a list of shareholders and directors be published once a year, that a meeting of shareholders be held once a year, that all contracts relating to the issue of shares or debentures shall be published, and that if a prospectus is printed and circulated it shall be filed with the other statements herewith enumerated, at Somerset House. Companies are not bound to issue reports or balance sheets, and if they do they need not distribute them to anyone but shareholders.

I would ask: how can the directors of a business be asked by law to issue a minute analysis of its trading account? To do so would be socialism pure and simple. That English mining companies issue such full reports and thus take shareholders and the public into their confidence has nothing whatever to do with the law of the land, but it is due to the general feeling that, unless there are special circumstances to prevent it, the policy of publicity is the right one in mining operations.

Also, I would point out that the laws governing English companies and mining operations are not "nearly uniform throughout the British Empire." In Australia public companies have to issue different returns from what they do in England. In fact, there is plenty of 'home rule' in English colonies.

London, November 16.

- Edward Walker.

Aluminum for Reducing Iron.

The Editor:

Sir—Referring to the article by W. H. Seamou on the 'Use of Aluminum to Reduce Iron Solutions,' of which an abstract is given in your issue of November 28, I wish to add my testimony to the usefulness of the method. It is an excellent one, but is not at all new. As much as eight years ago, when I was with a large copper company in Mexico, I was using aluminum for the reduction of iron in sulphuric acid solutions, and I used the method constantly for two years, during which time I made hundreds of iron determinations, and I believe that the method was then quite well known to chemists.

An improvement in iron titrations, however, which is not so generally known, but which is certain to be of great value to technical chemists, is the use of phosphoric acid to counteract the bad effect of hydrochloric acid when titrating by potassium permanganate. The method (first published by myself in the Western Chemist and Metallurgist in November, 1907), requires the following conditions. The iron solution must have only a small amount of free hydrochloric acid. This condition may be established by neutralizing the excess with sodium carbonate or with ammonia; an excess of not over 5 c.e. HCl (sp. gr. 1.20) is permissible. The solution may be reduced either by powdered zinc (the reduction being practically instantaneous), or by sodium sulphite, aluminum foil, or granulated lead. The two latter reducing agents are the most convenient. Stannous chloride cannot be used. Powdered zinc (zinc dust) and sodium sulphite give the best reduction in a nearly neutral solution, while granulated lead works with equal rapidity in a strongly acid solution or in one nearly neutral. For aluminum the solution must be more highly acid. After reduction the solution is cooled rapidly and decanted from the lead or aluminum; cold water is added to make the volume about 300 c.c., then 5 c.e. if syrupy phos-
phoric acid (sp. gr. 1.7) is added, and the solution is titrated by permanganate.

The results are exceedingly accurate. I have proved the method to be perfectly reliable, and have been using it constantly for more than a year, frequently running comparative tests by the standard bichromate method, with stannous chloride.

GEORGE J. HOUGH.

Selective Gold Solvent.

The Editor:

Sir—Is there a solvent for gold equal to cyanide of potassium or sodium, for analytical purposes, that will not attack iron or alumina. It is not a question of economy in commercial treatment, but to determine the presence of gold and its possible extraction.

LAY MINER.

New York, December 5.

A National Newspaper.

The Editor:

Sir—I have read with a great deal of interest the editorial in the last number of your journal on the need of a national newspaper; I believe that you have sounded the key-note of a method for educating the people more potent, at least along many lines, than the university itself. It is anomalous that in this country, which rightfully boasts of enormous bequests for educational purposes, the de-educational character of the average newspaper, to mention only one of the many charges that may be legitimately preferred against the press, has not been more generally recognized and more severely condemned, and that so little of practical value has actually been attempted to lessen the evil.

During the four years of their more mature life a few of our young men and women are taught in the universities the nearest approach to truth that the best thought, acting with the purest motives, can give. For the remainder of their lives these few, together with the great mass of the people, are constantly fed through our daily press with willful misrepresentations, corrupting suggestions, fawning synecophany, baseless superstition, misleading science, and general error. It is difficult to over-estimate the power for good that would result from giving the people an opportunity to read newspapers conducted on same lines. Universities, libraries, and hospitals are built and endowed by public-spirited philanthropists. What patriot will make possible, by suitable endowment, the publication of independent daily newspapers, within the reach of all, that shall fearlessly print the truth, the whole truth, and nothing but the truth?

C. L. WHITTLE.

Boston, December 4.

Drills for Quarry Work.

The Editor:

Sir—I note 'Halifax's' request for information regarding drills for quarry work, in your issue of December 5. During the past two years I have been using a Davis Calix drill for boring prospecting holes in firm sandstones and shales; during this time I have bored upward of 24,000 ft. of holes, averaging about 300 ft. each. The holes have all been vertical and from the surface, using tempered steel rotary bits, producing 2½-in. core from a hole a little less than 4 in. diam. We operate the drill with a gasoline engine, with water under natural pressure to raise the finer borings. We have operated the drill continuously, with two shifts of 12 hours each, and make as high as 40 ft. in 24 hours, under favorable conditions, averaging 30 ft., including time occupied in moving. Holes are bored 50 to 100 ft. apart. The deeper the hole, the slower the progress. This drill should work well for quarrying in favorable rock, but the saw-tooth bit will not stand very hard rock; the makers recommend a chilled-shot bit for hard rock, but we have no occasion to use it. I shall be pleased to give further information regarding our work, upon request.

B. M. NEWCOMB.

200 Davis St., San Francisco, December 8.

Copper Deposits of White Horse.

The Editor:

Sir—In your issue of December 5 appears an article under the above title. I wish to correct the information you obtained relative to the gold values contained in the ores of the Arctic Chief mine.

Sample shipments aggregating 737 tons of ore have been made from this property to the Crofton, Tye, and Tacoma smelters; returns from same show an average of 0.194 oz. gold, 1.54 oz. silver, and 4.45% copper per ton.

CHAS. P. ROBINS.

Spokane, December 10.
 PRESERVATION OF TIMBER.

Written for the Mining and Scientific Press
By F. H. Mason.

The preservation of timber has become an exceedingly important problem, not only because there is economy in using timber that by special treatment has been rendered less liable to rot in places where it is particularly prone to the ravages of decay, but also because the consumption of timber in modern industry threatens the annihilation of our forests.

The treatment of timber with antisepsics, with a view to preserving it from decay, dates back to the commencement of the eighteenth century, when timber was immersed in a solution of corrosive sublimate. The strength of the solution used was from 0.75 to 1.5%, and the timbers were allowed to remain in this solution from 1 to 30 days, the length of time varying with the dimensions of the timbers. About the middle of the eighteenth century copper sulphate solutions of similar strength to those of mercuric chloride were used for preserving timber. Finally, in the early part of the nineteenth century zinc chloride was tried, and although little used at first, it came into considerable favor as a preservative. While a number of other salts have been used from time to time, the foregoing have proved to be the most useful, and they have all been applied with success. The objection, however, to all of them is that the antisepic salts left in the timber are soluble in water, having been originally conveyed there by that medium, so that when the timber is subjected to leaching action, as in wet mines, this form of treatment is not applicable. It is true that in the ease of some antisepsics a small portion of the salt is chemically changed by the timber and rendered diffusely soluble, but it is not rendered sufficiently insoluble to withstand the leaching action of water in wet mines, especially if the mine waters are acid, nor is enough of it so chemically changed to form a preservative if the more soluble portions are leached out. It will undoubtedly occur to many readers, as it has to the writer, that the difficulty in connection with the leaching out of the antisepic salts by mine waters might be overcome by precipitating a difficulty soluble poisonous salt within the timber, a salt which, while being soluble enough to be poisonous, is sufficiently insoluble to be unaffected by leaching with mine waters. This could be accomplished by double immersion, preferably under pressure, and partly drying the timber between the two immersions. A number of combinations of salts will suggest themselves for this purpose. Timber has been rendered effectively fire-proof by the precipitation of diffusely soluble salts within its pores, and there appears to be no good reason why it should not be rendered proof against decay by a similar process.

Creosote appears to have been first tried as a preservative for timber at the beginning of the nineteenth century. The early experimenters, wishing to economize creosote and at the same time obtain an even impregnation, attempted to use the creosote in a gaseous form. The boiling points of creosote, however, being considerably above the temperature to which it is possible to heat wood without destroying its fibre and greatly diminishing its strength (it is not considered safe, from an engineering standpoint, to heat wood above 250° F.), caused these efforts to fail. An attempt was next made to force creosote into timber by the aid of superheated steam; this too was doomed to failure, for unless the creosote was heated to a temperature above that at which it would not injure wood, only the more volatile constituents of the creosote were carried by the steam beyond the immediate vicinity of the surface of the timber. It remained for Brent, a metallurgist, and at the time (1831) director of the Paris Mint, to be the first to suggest the process of filling timber with creosote by immersion under pressure. The process, modified by Bethell and afterward by Burt, is in use in many parts of Europe today. The timber, which has usually been seasoned, is packed on iron trucks and run into wrought-iron cylinders from 6 to 8 ft. diam. and from 30 to 100 ft. long. The cylinder is then hermetically sealed and the air pumped out until the gauges show a vacuum of from 20 to 26 in., which is maintained for some time, in order to get the greater portion of the air and moisture out of the sap canals. Creosote at 120° F. is then allowed to flow into the cylinder, filling the partial vacuum, and when the cylinder is full it is put under a pressure of from 100 to 150 lb. Gauges show the quantity of creosote that passes into the cylinder; the capacity of the latter and the quantity of timber within it being known, it is possible to pump the exact amount of creosote demanded by the specification. The creosote is kept under pressure for several hours and maintained at a temperature of 120° F. by steam coils. The disadvantage of the foregoing process is that it is unsuited for freshly cut timber, or timber that is soaked with water. To overcome this, Boulton added a dome to the treatment cylinder; at the top of the dome he placed a pipe connecting with the vacuum-pump. The timber freshly cut or water-soaked from the ponds is loaded into the cylinder and the air exhausted, as previously described. Creosote at 212° F. is allowed to flow in, and the vacuum-pump kept working until it rises to the base of the dome, a glass gauge indicating when it reaches that point. The creosote is maintained at 212° F. by steam coils, and the water-vapor driven from the wood rises into the dome, and is sucked away by the vacuum-pump. It is claimed that 10 lb. per cu. ft. can be charged into the timber by this method; there must, however, be a considerable loss of naphthalene, and unless the original creosote contained an unusually large proportion of that substance, I should expect the creosote in the timber to be deficient in naphthalene.

At Norfolk, Virginia, the Norfolk Creosoting Co.'s plant consists of two batteries, the one of three, and the other of two cylinders. These cylinders are from 120 to 125 ft. long and from 6 to 6½ ft. diam.; they are set in brick and are provided with heavy steam-tight doors, which are fastened in place by

* I desire to thank Mr. C. E. W. Dodwell, engineer to the Dominion Government at Halifax, for the details of the creosoting plant at Norfolk, Virginia.

lug-boirts. Each battery is provided with a large vertical vat set in brick; in this the creosote is heated, and two vertical storage vats (supplied with gauges to indicate the amount of creosote contained in them) in which the creosote is measured before delivery into the treatment-cylinders. These vats and the treatment-cylinders are provided with steam coils, so that their contents may be maintained at any desired temperature.

In all large contracts it is customary for the buyers to be represented by an inspector, whose duty is to see that the proper quantity of creosote is forced into the timber, and also that the creosote is of the quality specified. The timber to be treated is measured and run into the cylinders on iron cars, the cubic contents of which are known, the doors are bolted in place, and the cylinder is filled with steam at a temperature of from 250 to 275°F. (in the case of water-soaked timber the temperature is allowed to reach 285°F. for the first half of the period), and under a pressure of from 35 to 55 lb., and maintained under these conditions from 5 to 7 hours. The cylinder is then emptied of water and sap through a draw-off cock at the bottom, and the vacuum-pump is started, a vacuum of not less than 20 in. being maintained from 5 to 8 hours. The temperature within the cylinder during this period is kept between 100 and 130°F. The draw-off cock is once more opened and the cylinder is entirely emptied of water and sap; the vacuum-pump is then put into operation until a vacuum of about 25 in. is obtained. The creosote in the storage vats is now measured in the presence of the inspector, and is then allowed to flow into the treatment-cylinder, and the vacuum-pump is kept going until the latter is quite full. The inspector now draws off a sample from a cock at the side of the cylinder and makes a fractional distillation of the creosote; if the latter is of the specification demanded, a pressure of from 30 to 150 lb. (varying with the amount of creosote with which the timber has to be filled) is maintained until the gages in the storage vats indicate that about the proper quantity of creosote has been forced into the timber. The creosote is maintained at a temperature between 130 and 180°F. during the treatment. A pressure of 30 lb. for three or four hours is generally sufficient to charge the timber with 10 lb. of oil per cubic foot, and cause a penetration of 1½ in. from all surfaces. A charge of 25 lb. per cu. ft. requires a pressure of 100 lb. for 8 to 10 hours. When the treatment is completed, the creosote is pumped from the treatment-cylinder back into the storage vats and the gauges read in the presence of the inspector, the difference between the first and the final reading indicating the amount of creosote that has been forced into the timber. It is generally arranged that the temperature of the oil shall be the same for both readings, otherwise a correction would have to be made for the difference in temperature.

With regard to the oil used, the Norfolk Creosoting Co. guarantees that all oil shall be dead oil of coal tar, containing not more than 1.5% water, nor 5% of tar, nor 5% of carbolic acid. It shall not flash below 185°F., nor burn below 200°F. It shall begin to distill at 320°F., and the fraction distilling between that temperature and 410°F. shall not be more than 20% of the whole volume. The fraction distilling between 410 and 470°F., which is taken as naphthalene, shall not be more than 60% nor less than 40% of the whole volume. It shall be fluid at 118°F., and at that temperature its density shall lie between 1.015 and 1.05.

The following may be considered to be an average fractional distillation of the dead oil of tar used while the Norfolk Creosoting Co. was filling an order for the government of the Dominion of Canada:

The fraction distilling between 210 and 235°C. and half of the fractions distilling between 205 and 210°C and 235 and 240°C. are taken as naphthalene. I have found that this method of determining naphthalene gives results from 3 to 6% higher than the method of separating by filtration from the combined distillate.

Discussion has arisen from time to time as to which of the various ingredients of creosote is responsible for its property of preserving timber. In the early days the tar acids (carbionic and cresylic acids) were supposed to be wholly and solely responsible for the preserving powers of creosote, but analyses of railway ties that had been in use for a number of years, and which were in perfectly sound condition, showed only traces of these acids. Such a result was rather to have been expected, because both acids are volatile at ordinary temperatures and are also appreciably soluble in water, while neither of them enters into permanent combination with albumen or woody fibre. After the apparent exploding of the theory that the tar acids were the essential ingredients of creosote necessary for the preservation of wood, the pyridine series of hydro-carbons came into favor, especially acridine, and specifications demanded varying quantities of these ingredients. Today naphthalene is demanded, often in quantities in excess of that in which it occurs in ordinary dead oil of tar, so that it has to be added to meet the specification. Naphthalene is particularly demanded for timber that is to be submerged either wholly or partly. It is also demanded that the creosote shall contain a considerable amount (generally not less than one-fifth) of heavy oils fixed at a temperature of 600°F. This is specified because the heavy oils fill up the pores of the wood and prevent the volatilizing of naphthalene and phenols, and also prevent the infiltration of water and consequent solution of the tar acids. Nearly all specifications demand that the creosote shall have a density varying between 1.035 and 1.065,
the object of this being to prevent adulteration with crude mineral oil.

Creosote, or dead oil of coal tar, as it is more properly called, to distinguish it from wood creosote, is that fraction which distills over from coal tar between 204 and 404° C. or 399.2 and 779.2° F. The distillate is far from being of constant composition. It contains varying quantities of naphthalene, phenanthrene, anthracene, pyrene, chrysene, carbazole, benzthrene, and other solid hydro-carbons; carbolic and cresylic acid, and some of the higher phenols are invariably constituents, as are also basic substances of the pyridine series. The density of creosote usually lies between 1.02 and 1.05, but there are marked exceptions to this. The quantity and quality of creosote obtained from tars varies not only with the coals from which the tars are derived, but also from the manner in which the coals are coked. Thus, Lung found 1.53% of naphthalene in the tar obtained from coal coked in a modified beehive oven heated with external flues, and 7.69% of naphthalene in the tars from the same coal coked in an Otto-Hoffmann oven. While creosote commences to boil at 204° C., some of its ingredients are markedly volatile at ordinary atmospheric temperatures. This fact was vividly brought to my notice some years ago: I had been making some analyses of creosoted timber, and I put a piece 12 by 12 by 12 in. away in a tin box and pasted a piece of glazed paper around the joint between the box and the lid. When I opened the box some four months later, the lid and the sides of the box were covered with plates of naphthalene, which had volatilized from the timber. The temperature of the laboratory certainly never exceeded 90° F., and probably averaged about 65° F. The sample was an end piece of timber and saturated with creosote.

The industry of creosoting timber offers a tempting opportunity for fraud, not only by insufficiently ‘filling’ the timber, but also by adulterating the dead oil used. It therefore behoves purchasers to keep a careful watch on the product supplied to them, for a poorly filled timber or one filled with bad material may sometimes be even worse than an untreated timber. To be assured that an order of timber is filled with the specified quantity and quality of creosote is not an easy matter. The first essential is to get a thoroughly trustworthy and capable inspector, and it is necessary to corroborate his work by analysis of the treated timber, for the pipes connecting the feed from the storage vats are generally concealed, and if it were desired to do so, it would be possible to deceive any but a very inquisitive inspector.

By whatever process the timber has been treated, it will be impregnated an average distance from all external surfaces, and along the sap canals for some distance from the ends of the timber; therefore, in all but short timbers we should expect to find, and do find in sound timbers, that the heart wood in the centre of the timber and an area around it contains but little or no creosote (Fig. 1). Should the timber be shaken, that is, cracked in drying, creosote will enter the cracks and be conveyed to the heart of the timber. It will be evident that, with the exception of perhaps two feet at the ends of the timbers which will be saturated (that is, provided an honest endeavor has been made to fill the timber), no two sections (say, half an inch thick) cut from different parts of the timber will contain the same amount of creosote; so that, in order to get an average, it would be necessary to take a number of sections from different parts of the timber. In dealing with big timbers, 20 to 60 ft. long, on account of the cost, the purchaser is both to cut up even a single stick for the purpose of analysis unless there are distinct indications of fraud on the part of the manufacturer, and if the consignment were a big one, a single stick would be a poor proportion for a sample. It is apparent, then, that to attempt to obtain an absolutely accurate sample would not only be costly, but would probably be futile, and, after all, the object of the sampling and analysis is not to find the exact amount of creosote in a stick of timber so much as to find if the manufacturer is making an honest endeavor to live up to his contract. Taking into consideration the foregoing, the plan I have adopted is to find out at what lengths any of the timbers have to be cut, and going upon the basis that the greatest amount of creosote is to be found at the ends and the least in the middle of the timber, it is possible to select from the timbers that have to be cut a sample that will sufficiently nearly approach an average for the purpose desired. Having selected the timbers from which the sample is to be taken, it is always possible to have a section half an inch thick cut from them. These sections are placed in a tin and sealed, a piece of adhesive tape used by electricians being a good material to seal the joint between the box and the lid. When the samples reach the laboratory the centre of the heart wood, where there is least creosote, is taken as a centre and lines drawn to the sides of the section, every other, every third, or every fourth of the divisions thus formed (as the case may demand) is taken for the sample. The quantity to be taken for analysis is such that it will contain from 80 to 120 gm. creosote; this, after it is weighed, is cut into fairly coarse shavings with a metal plane, the shavings are put into the extractor, and when the apparatus is set up, the plane is rinsed
with alcohol, which is poured onto the shavings in the extractor.

The extractor I have used (Fig. 2) consists of three parts: 1. The flask, in which the solvents are boiled. 2. The cylinder containing the shavings. 3. The condenser, in which the vapors of the solvents are condensed. As a solvent I use a mixture of three parts alcohol and one part ether. As the extraction often takes 10 or 12 hours, it is advisable to place the flask on a self-filling water-bath, so that it may be left running during the night without the danger of causing fire. The cylinder is made of copper, tinned on the inside; it is about 4 in. diam. and 18 in. long, and terminates at the bottom in a funnel. The pipe of the funnel that goes through the cork of the flask is cut at an angle of about 60°, in order that the condensed solvent may fall from the point and not stop up the pipe. At a point where the funnel is about 2 in. diam. a piece of copper gauze is soldered. The lid of the extractor, which is conical in shape, it attached to the cylinder by a substantial brass screw and nut, the former being soldered to the cylinder, and the latter to the lid. The apex of the cone is cut off; a half-inch copper pipe, about 21 in. long, passes through it and projects about 1/2 in. on the inside, and is cut off at an angle of about 60°; immediately underneath this pipe is fastened the apex of a cone about 2 in. diam. at the base and held in place by three wires soldered to the inside of the lid. That part of the pipe outside of the lid is surrounded by a water-jacket to form a condenser. The object of the cone within the lid is to spread the liquid condensed in the pipe over a large area. The pipe at the bottom of the extractor passes through a bored cork into a Jena glass flask.

To make the assay, a quantity of shaving that will give from 80 to 120 gm. of creosote is placed in the cylinder and gently rammed down, the lid is screwed on, a thin sheet-lead gasket being placed at the joint. The flask is now connected and placed on the water-bath, and water is circulated in the condenser. A mixture of three parts alcohol and one part ether is poured in at the top of the apparatus, a little at a time, until the flask (which is of about 600 c.c. capacity) is from half to two-thirds full. The burner is then lighted and the extraction commences.

The principle of the operation will be evident; the vapors of the solvents rise up through the copper pipe into the cylinder. Some of these vapors will be condensed in the cylinder, some will pass through the cylinder and be condensed in the condenser, in either case the condensed solvents will pass through the wood shavings back into the flask, taking creosote with them. Thus, the same solvents are used over and over again, and each time they are condensed they bring a fresh portion of creosote into the flask, until the whole of the creosote is removed from the shavings into the flask. If there is much water in the timber it will be found necessary to change the flask and use fresh solvents after the operation has been going on for an hour, or possibly less, otherwise the bumping is likely to break the flask and ruin the assay. When the extraction is nearing completion, which will be evident from the condensed liquid dropping from the extractor being colorless, the flask must be changed and fresh solvent used. This is necessary on account of the fact that naphthalene, one of the principal ingredients of creosote, distills over in marked quantities with alcohol vapor from moderately concentrated solutions, but not appreciably from dilute solutions. When the extraction is complete the various extracts are all mixed together and the solvent separated from the creosote by distillation. When nearly all the solvent has distilled over, which will be evident from the rise in temperature of its vapor, the creosote is transferred to a tared hard-glass retort, of about 350 c.c. capacity, the retort is fitted with a Jena glass thermometer filled with nitrogen, and having a range of from 80 to 350°C, visible outside the cork. The bulb of the thermometer should reach within 1/8 in. of the bottom of the retort. The retort is now placed in an air-bath (Fig. 3), asbestos fibre or wool glass is packed around the neck and around the thermometer, and it is raised to a temperature of 100°C, and kept at that temperature until no further distillation takes place; it is then allowed to cool and is weighed. The distillate, which contains naphthalene, is measured and two or three lots of 10 c.c. are allowed to evaporate spontaneously in a tared dish, which is then dried in a desiccatior and weighed; this weight, less the tare of the dish, gives the amount of naphthalene in 10 c.c.; from it the quantity of naphthalene in the distillate is calculated, and added to the creosote found. The retort contains resin and other ingredients of wood soluble in alcohol and ether, as well as all the creosote; to separate the last from the former is not an easy problem; it is tedious and costly; but there is another way out of the difficulty which will meet the case. As I have already pointed out, the sampling is far from being accurate; under these conditions it is useless to carry the analysis to complete accuracy. Samples can be obtained from the manufacturers of the wood they are treating after it has been through the steaming process and before it has been creosoted; these samples can be classified into three or four grades by their appearance, and extractions made from them similar to that made of the creo-
soted wood. The creosoted timber to be analyzed is compared with uncreosoted samples and deduction made accordingly for resin, etc. Fractional distillations are made of the resin and sap extracted from untreated timber, in order to make corrections of fractional distillations of creosote containing the same. The wood shavings from which the creosote has been extracted are dried and weighed, and the difference between their weight plus the creosote, resin, etc., obtained, and the weight of the original sample taken, is the weight of water in the wood taken. With regard to the analysis of creosote, this is often not left to the analyst's discretion, the specification demanding certain tests rather than an analysis. A favorite English specification, originally devised by Sir Frederick Abel, demands:

1. The density shall not be less than 1.035 nor more than 1.065.

2. The creosote shall be liquid at 100° F., and no solids shall separate until the temperature falls below 93° Fahrenheit.

3. The creosote shall contain not less than 25% of material not volatile below 600° Fahrenheit.

4. The creosote shall contain not less than 8% of tar acids, which are to be determined by washing the distillate obtained from No. 3, three times with caustic soda solution of a density of 1.2 and allowing the mixed washings with dilute sulphuric acid (1 acid 3 water) and the tar acids to separate in a separating funnel. The separated acids to be dissolved in caustic soda solution, filtered through glass wool, the filtrate acidulated with dilute sulphuric acid, placed in a narrow graduated glass tube, and the percentage of tar acids by volume read.

5. The creosote to contain not less than 25% of naphthalene, which is to be determined from the distillate from No. 3 by cooling it to 32° F., filtering at that temperature, and pressing the residue between absorbent paper, and weighing.

In Canada and America the custom is to demand a fractional distillation. A demand of from 25 to 50% of naphthalene is made, and also that the residue fixed below 316° C. shall not be less than 20 to 30 per cent.

Besides, for the purpose of mine timber, railway ties, and wharf posts, creosoted timber might be advantageously used for sills of pit-heads, aerial tramway towers, many buildings, and a number of other purposes. The butt ends of telegraph and telephone poles are frequently creosoted in Europe. Whatever be the use to which creosoted timbers are put, one important point should be borne in mind: when a timber is cut, or when notches or mortises are cut in it, these often reach beyond the protected portion of the timber, and unless these places are well coated with creosote to prevent the inroad of rot at these points to the interior of the timber, the value of the creosoting is to a great extent lost. A pot of creosote and a brush should form part of a timberman's kit when working with creosoted timber.

With regard to the quantity of creosote with which it is necessary to charge wood in order to insure it against decay, indisputably the nearer it approaches saturation the longer will be its life, but it is often not practicable to fill wood to this extent. Owing to the fact that a considerable quantity of creosote enters the wood through the sap canals, a much greater amount of creosote is found in the ends than in the middle of timbers. The manufacturers only guarantee to put a specified quantity of creosote into an order of timber; they do not and cannot guarantee to fill every cubic foot with the specified amount of dead oil. For this reason, when making out a specification it is necessary to take the length of the timber into consideration. When incisions have to be made in timbers at regular known points, they should be made before the timber is treated.

It is generally conceded that a well creosoted timbey (say, a timber which is impregnated with good heavy dead oil of tar for not less than two inches from all surfaces) is better able to withstand the ravages of decay under all atmospheric conditions than a timber treated by any other process. On the other hand, the great disadvantage to creosoted timber, especially for use in mines, is its inflammability, and in the event of fire, the suffocating aerial fumes evolved preventing access to the neighborhood of the fire. Timbers treated with mineral salts, on the other hand, are usually much less inflammable than untreated timbers, some of them being practically fire-proof.

Occasional tests should be made of the strength of creosoted timbers, because there is no doubt that a number of manufacturers exceed the safe limit of temperature in 'steaming' the timber, and thereby considerably impair the strength of the product.

**Cementation index** is the name given to a formula designed to express quantitatively the relation between the composition of cements or raw materials and their hydraulic value and strength. The formula is as follows:

\[
I = \frac{2.8SiO_2 + 1.1Al_2O_3 + 0.7Fe_2O_3}{CaO + 1.4MgO}
\]

In which I is the cementation index and the component parts are expressed in percentages of the total weight. The formula is particularly valuable for investigating the probable adaptability of raw materials for the manufacture of cement or hydraulic lime, as well as for calculating the mixtures of untried raw materials. The ideal Portland cement will have a cementation index of unity, and for most good cements now on the market the value is between 1.00 and 1.20. A high cementation index means a high-lime and low-clay cement, and a low index indicates the reverse. The value for natural cements will generally be between 1.15 and 1.90, and for slag cements between 1.60 and 1.90. It must be noted, however, that in the case of raw materials the cementation index indicates what may be done with proper methods and manipulations, but that many factors enter into the final result. For instance, a material having a cementation index of 1.05 might be a hydraulic lime, a natural cement, or a cement of the Portland type, depending chiefly on the temperature at which the raw material was burned.
NEW PLACERS IN ALASKA.

Three new localities for placer gold in the lower central part of the Yukon valley, brought to the public notice within the last two years, are of particular interest because they show that the gold-bearing formations of the valley are of much wider extent than has generally been supposed.

Last summer A. G. Maddren, of the U. S. Geological Survey, made reconnaissance trips to these localities, which are known as Gold Hill, Ruby Creek, and the Innoko.

The Innoko district is more widely known and discussed than the Gold Hill or the Ruby Creek district. Since the discovery of placer gold in paying quantities, in 1906, on some of the headwater tributaries of Innoko river, that part of Alaska has received more attention from prospectors looking for new fields than any other district in the Yukon valley. Probably as many as 2000 men have visited the Innoko country and remained there for the whole or part of a season. Many of these men have come from the older placer districts up the Yukon, especially from Fairbanks; some have come from Nome, and a few from the smaller settlements on the lower Yukon.

The Innoko, the lowest noteworthy tributary of the Yukon entering from the left, is about 500 miles long, and has been the principal route to and from the diggings on its headwaters. During 1906 small stern-wheel steamer-boats ran up the river to Dikhkakat, about 250 miles from Anvik, on the Yukon. From Dikhkakat it is 190 miles farther by the river to Ophir, the principal settlement of the diggings, and this distance is traveled in poling boats that will hold about one ton of freight. The most serious drawback to prospecting in the Innoko country is the difficulty and cost of getting supplies to a centrally located distributing point convenient to the creeks on which pay gravel has been discovered. So far most of the provisions have been shipped into the district from Fairbanks, and by the time the freight is delivered at the town of Ophir the transportation cost has reached the enormous sum of $500 per ton.

The Innoko country has been staked in a wholesale manner, about 1200 locations being on record. Of this number only about 25 claims were worked during the summer of 1908, and practically all of these were on Ganes, Little, and Ophir creeks. About 150 persons are now wintering in the Innoko district.

The name of Gold Hill is applied to an area in the central Yukon valley, about 25 miles below the mouth of Tanana river, that lies along the north side of the Yukon and extends westward from the western slopes of the valley of Tozitna river to the higher mountains north of the United States telegraph station called Birches. Roughly, the district embraces an area extending 30 miles east and west and 20 miles north and south, covering about 600 square miles. Most of this area consists of mountains that form a divide extending east and west about midway between the main courses of the Yukon and the headwaters of the Melozitna. This divide separates the region into two areas that are drained to the north and south by creeks of moderate length and volume.

The principal southward-flowing creeks, named from east to west as they join the Yukon, are Grant, Illinois, Mason, and their tributaries; those flowing northward into the Melozitna, named in the same order, are Moran, Eureka, Hudson, Langford, and Tiffany creeks and their tributaries. It is in the gravel deposits of these creeks that the placer gold is found. Practically all the alluvial ground on these streams has been located for placer mining. The locators are mostly association groups that enable a few men actually present on the ground, presumably provided with powers of attorney from a number of absent persons, to tie up completely many thousands of acres of alluvial deposits bearing placer gold. The result of this practice is that many intending workers are unable to acquire ground rights, and that the healthy growth of the placer-mining industry is being retarded in a very discouraging manner.

Open-cut ground-slicing operations have been be-
COPPER-GOLD SMELTING AT MAGISTRAL.

Written for the MINING AND SCIENTIFIC PRESS
By Robert Linton.

The Magistral mines, owned by the Laster Mining & Smelting Co., are situated near Santa Maria del Oro, Durango, 50 miles from Rosario, on the Mexican Central railroad. They yield a gold-silver-copper ore, about 85% of the total gross value being in the gold. After more than 18 years of disappointing results, due to the failure of different methods of ore-treatment, it was decided to resort to copper smelting, using the copper as a collector for the precious metals. By courtesy of R. W. Bissell, general manager for the company, who designed and built the present smelter, I am permitted to give the following account of the plants and practise.

The history of the early operations of the company records a strenuous endeavor to keep away from smelting. This is natural, as the running of a smelter 50 miles from a railroad is a costly undertaking. The first plant was a 40-stamp mill with plate amalgamation, but the ore was not sufficiently free-milling to yield a satisfactory recovery. Chlorination was subsequently employed, then cyanidation, but neither proved successful.

The first attempt to apply smelting methods was made about 8 years ago. At that time the bulk of the ore mined was high in sulphur, and this suggested the possible application of pyritic smelting. Two cylindrical blast-furnaces, 36 in. diam., with hot-blast stoves, were built and run for several months on the richer sulphide ore, the charge carrying about 30% sulphur. As the results were not satisfactory, the furnaces were torn down and two others of the same general type built, 42 in. diam., these in turn being replaced by two 48-in. furnaces. A number of modifications were introduced, as experience in operating suggested, but the best results were nevertheless far from satisfactory.

Two furnaces were then built on the lines of copper matte blast-furnaces, 42 by 120 in. at the tuyeres. They reached a capacity of 100 tons of charge per 24 hr., or 2.9 tons per square foot of hearth area, on a charge carrying 22% sulphur. The results were generally much more satisfactory than has been obtained in running the cylindrical furnaces, sufficiently so to demonstrate the entire feasibility of smelting the ores, even with the long overland haul of the coke and matte. It was therefore decided to build a new smelter of increased capacity and improved design, which is now in operation.

The smelter is at the Cocomera mine, from which the bulk of the ore comes at present. It occupies a central position for the whole group. It stands on a hillside, affording ample room for slag-dumps below and ore-bins above. The latter have not been built, as yet, in accordance with the original plan, and the ores are stacked and mixed on the open patio. The system of ore-bins when installed will permit of better bedding of the charges in advance of requirements, which will be of material benefit to the plant.

The smelter has three blast-furnaces, designed by Mr. Bissell, and Frank B. Hine, smelter superintendent. Each is 40 by 168 in. at the tuyeres, and has McDonald hot-blast stoves. The sides of the furnaces are vertical for 7 ft. above the tuyeres, which is the ordinary height of the charge column, and the receiving plate runs from this point on a 45° slope to the

Tap-Floor, Magistral Smelter.

Smelter at Santa Maria del Oro, Durango.
charging-floor 3 ft. above. The long receiving plates retard the fine material in the charge, which in consequence falls along the sides of the furnaces, while the coarser portion of the charge is thrown to the centre. While the charge column is usually held at a height of 7 ft. when the charge is highly basic, the furnace is charged full to the floor-level, in order to afford the proper desulphurizing zone before the charge reaches the smelting zone. In a new furnace the spouts to the settlers are at the bottom of the furnace, so that there is no crucible except such as is formed by the wear of the bottoms. The latter are built 30 in. thick, all of local brick except immediately around the spouts, where chrome brick is the only sufficiently refractory material yet found.

Each furnace is provided with two settlers, one on each side, in order to facilitate repairs without inconvenience or interruption in operating. The settlers are circular, 69 in. diam., 36 in. deep, inside of the fire-brick lining, when new. The shells are of 5 3/8-in. boiler plate. There are two slag-taps set equidistant from each other and from the furnace-spout, the bottom of the taps being 6 in. below the top of the shells. The matte-taps are level with the bottom of the settlers. The maximum height of matte in the settlers is therefore 30 in.; 10 in. is usually drawn off at a time, and 30 in. left in the settler. The average life of the linings, which are built of local brick, is 26 days. Water to the jackets flows under an 18-ft. hydraulic head through an 8-in. pipe-line from the reservoir, with a 6-in. connection to each furnace, a 3-in. branch leading from this to each jacket. From the top of the jacket the water flows through a 2-in. outlet-pipe and discharges into a tank from which it is returned to the reservoir by two 4 by 5-in. Gould pumps. The water is lifted vertically, discharged into a launder in which it flows to the cooling tower, and thence back to the reservoir. Each furnace uses 700 gal. water per minute, fed at 10 to 12° below the temperature of the atmosphere and discharged at 160 to 180° F. The free discharge from the 2-in. outlets is so situated as to be conveniently observed from the charging floor. The consumption of fresh water is 1000 cu. ft. per 24 hr. for each furnace, which includes what is used for sprinkling and cooling on the charging and top floors, as well as evaporation.

There are 16 tuyeres on each side of the furnace, 5 in. diam., bushed to 4 3/8 in., set 10 in. between centres, each provided with a quick-opening gate-valve. The bustle-pipe is of No. 8 gauge iron, 24 in. diam.; one branch pipe, 32 in. diam., leads to each furnace from the blast-main; the latter is 52 in. diam., which is larger than is required for the present furnace capacity, the object being to add more furnaces later. The blower plant has two No. 8 1/2 Root blowers and one No. 7 1/2 Connersville type, all geared to 150-hp. slow-speed G. E. induction motors. The ordinary pressure at the tuyeres is 11 oz., with 16 oz. at the blowers. With very fine charges the pressure rises to 15 oz. at the tuyeres, with a corresponding increase at the blowers. Each furnace uses 12,500 cu. ft. of free air per minute, practically 100,000 cu. ft. per ton of charge. This high consumption of air is required to maintain a sufficiently oxidizing condition in the furnace. The blast is passed through McDonald hot-blast stoves, where it receives a superheat of 70 to 80° F. before entering the furnace. The loss in pressure between the blowers and the furnaces is chiefly due to the friction loss in passing through the stoves.

The stoves also serve the purpose of dust-chambers. Downdrafts take directly from the top of the furnaces to the stoves, and the bulk of the fine-dust is deposited in the space underneath the heater-pipes, which space is cleaned out periodically. What dust is not caught here settles on the bottom of the draught-tube that is built up the side of the hill, back of the smelter. The flue is 7 ft. wide and 8 ft. 2 in. to the spring of the arch, with a semi-circular arch, the total length being 1100 ft., and rising 136 ft. above the charging floor. A stack at the top 15 ft. high, makes the total height of the draught column 151 ft., this being ample for the needs of the plant. The large flue-section, 76 sq. ft., permits the gases to travel through slowly and the dust to settle quite completely.

The slag is run into elliptical slag-pots mounted on trucks, holding 16 cu. ft., hauled by mule teams over a surface tram to the slag-dump. The matte-pots, holding 2 cu. ft., are east of mild steel and mounted on two-wheeled hand-trucks. Cast-iron pots were formerly used, but as they gave a great deal of trouble from cracking, steel pots were tried and found satisfactory during the 9 months they have been in use. All of the fire-brick used for the settlers and furnace-bottoms (excepting around the spouts) are made on the ground from clay mined on the company's property. The brick cost $15 gold per thousand, the clay being ground and the brick molded by hand. Fire-brick imported from the United States cost $95 per thousand at the smelter. The local clay is also used for tap-hole stoppers, and in all work around the furnaces for which fire-clay is required. Slag-brick are also made from the more silicious low-lime slags, and are used for building purposes. They are 8 by 22 by 4 in., cost $5 per thousand to make, and produce a very neat and durable building.

The furnaces are usually charged at intervals of 15 min., 4080 lb. of raw ore going in with each charge. The ore is wheeled in two-wheeled buggies from the patio and weighed. Crusts or accretions are barred down from the charging floor in the usual manner. The entire smelter force is Mexican, with the exception of the superintendent, night foreman, and one repair-man. These are from the United States.

The ores are separated into four general classes, based on their composition as affecting smelting operations, namely, oxidized ore (acid), silicious sulphide (acid, or self-fluxing), sulphide (basic), and lime spar (fluxing). They furnish the necessary variety for making up the furnace-charges without any further additions. Each of the above four classes exhibits considerable variation in composition and metal content, but the following may be considered fairly representative:
By proper selection of ores, through control of mining operations and bedding of ores in advance of requirements, it is possible to maintain a quite uniform charge. Lack of ore-bin facilities hinders this at present; consequently there is considerable variation in the composition of the charges, and close supervision is required to keep the furnaces up to capacity. A certain amount of low-grade matte is always made, which must be concentrated by roasting and smelting to bring it to shipping grade. It may eventually prove desirable to concentrate the ore prior to smelting, but in present practice the low-grade matte is a useful addition to the charge, and renders available a larger proportion of the acid ores. Any foul slag from the furnaces, all barrings, and the like are added to the charge. Owing to the high gold content of the matte, the waste of any "metallies" is scrupulously avoided. West Virginia coke is used for fuel in the proportion of 10% of the total charge fed to the furnaces. The shipping matte contains 15 to 17% copper and $110 to $135 gold per ton. The charge sheet shown below may be taken as representative of the furnace operations.

The slag-losses calculated back to the original ore-charge amount to 74.6c. gold, and 2.14 lb. copper, per ton of ore. The flue-dust losses amount to 67.5c. gold, and 1.19 lb. copper, per ton of ore charged. The

months’ operations show a total furnace loss, calculated from the difference in total value between the furnace charges as shown by assay and the settlement value of the matte, of $1.06 gold, and 2.16 lb. copper, per ton of ore smelted, being somewhat less than the loss shown above. For the same period the recovery of copper was 83.3%, and of gold 87.4%. A portion of this time the furnaces were hampered by insufficient blast, by reason of an accident to the main blast-pipe. The normal recovery is probably more nearly represented by the figures on the charge-sheet, which show a recovery of 89% of the gold and 84.7% of the copper.

ELECTRIC SMELTING OF IRON ORE.

By C. E. Elwell.

*The seventh run of the single-phase experimental electric furnace of the Noble Electric Steel Co., at Heroult, Shasta county, has just been completed. The furnace was run from 7 a.m., August 25, until 7 p.m., October 3, a period of 39 days, and was shut down while running at its best, in order to obtain data relating to the exact distribution of the charge when the furnace is running normally. In this period a total of 35 tons of pig-iron was produced, with an energy expenditure of 11.34 kilowatt-years, or an average of 0.324 kw.-yr. per ton of pig-iron produced.

The run may be properly divided into two parts. For the first 25 days the 160-kw. transformer was used, and 14 tons of iron were produced, with an expenditure of 6.09 kw.-yr., or an average of 0.435 kw.-yr. per ton. It appeared that this was too little power for the furnace, and so a 500-kw. transformer delivering current at a pressure of 50 volts, was connected to the furnace. This allowed the furnace to take all the energy which it required at this voltage, and it promptly took about 200 kw. It was not found to be so advantageous to have a fixed voltage as to have a variable, as it was difficult at times to get the furnace to take its full quota of energy, for example, after tapping. In spite of this, in the 14 days of the period the furnace made 21 tons, with an expenditure of 5.35 kw.-yr., or an average of 0.250 kw.-yr. per ton. The furnace was then shut down, as before noted. The summary for the last seven days of the run shows that an average of nearly 1½ tons of iron was produced per diem, at a cost of 0.273 kw.-yr. per ton, or $4.20 per ton for electrical energy. If this figure can be obtained with such a small furnace as one of 200-kw. nominal rating (the average load was 154 kw.), in which quite a percentage is given up in losses, then the prospects for the realization of a better figure with a larger furnace are indeed bright.

The figure for the whole run, from the time current was switched on until it was switched off, was 0.324 kw.-yr. per ton, or $5.18 per ton for electrical energy. The legitimate figure to take, however, is the one for the second period, where 21 tons were produced at an average expenditure of 0.25 kw.-yr. per ton, or $4 per ton for electrical energy.

The Noble Electric Steel Co. is now building a 1500-kw. furnace, which, on the basis of the above results, ought to have no difficulty in producing 15 tons per diem as a minimum, and 20 tons ought not to be out of the way. Taking into consideration the low cost of furnance, labor, and electrical energy, there seems to be no reason why iron cannot be made at the plant for $16 per ton, a conservative estimate. The problem has not been one of making pig-iron so much as to build a furnaee which would stand the excessive internal heat. After a run of 39 days it seems as if this is also solved.

The iron ore for smelting is being furnished by the Shasta Iron Co., from a mine on the Pit river. The ore is magnetite, carrying from 50 to 75% iron.

*Abstracted from Journal of Electricity, Power, and Gas.
CALUMET & HECLA COSTS.—I.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. Austin.

The Calumet & Hecla company has divulged so little information regarding its operations that the following, taken from testimony given in a suit brought by A. S. Bigelow against the Calumet & Hecla Mining Co., before Judge Knapp of the U. S. Circuit Court for the Western District of Michigan in the year 1907, is of unusual interest and value.

Complaint was made by Mr. Bigelow, a holder of 1000 shares of Oseola stock, that the Calumet & Hecla Mining Co., having acquired 20,000 shares of such stock, was about to get control of the Oseola Mining Co. to monopolize the output of “prime Lake Copper, which he stated was used by the U. S. Government and others to the exclusion of electrolytic copper.”

The copper production of the world in 1906 is given at 1600 million pounds, of which the Americas (North and South) produced 1400 millions, and the United States 914 million pounds, 60 to 70% being electrolytic. From one fourth to one fifth of this, or 226,700,000 lb., is produced by the northern peninsula of Michigan, and of that quantity, only 167 million pounds could be called Lake copper, as quoted at New York. This was credited to various mines, as follows:

167,250,000

Thus two-thirds of the copper is produced by the Calumet & Hecla alone.

The present value of the Calumet & Hecla property is given at $90,000,000. It consists of the Calumet and the Hecla mines, and a portion of the Oseola lode extending for a distance of 2½ miles, yielding a conglomerate ore and an amygdaloid ore, respectively. The company is interested in other mining properties, a railroad, by which the ore is delivered to its concentrating mill on Torch lake, a stamp-mill at Lake Linden, 5½ miles distant, and a smelting plant a mile beyond, at Hubbell. Besides this, it owns a smelter and an electrolytic refinery at Buffalo, N. Y. It has acquired 50,000 acres of woodland, in addition to mineral lands covering 2680 acres. The Oseola amygdaloid lode of the C. & H., adjoining the Oseola property, consists of 640 acres. The total lands owned by the C. & H. aggregate 65,650.37 acres.

The equipment, consisting of the mine plant, the railroad, the mill, and the smelters, may be reckoned at 15 to 16 million dollars, and there are 4500 men employed. The machinery, worth ten million dollars, if the mines were exhausted, would be worth 25% only of its present value. The railroad has cost $500,000, and, if it were sold to be removed, might bring 15 to 20% of its present valuation.

In 1873 the company put out 290,000 tons of ore carrying 5% copper, while in 1906 the ore contained a little over 2%, the richness decreasing as the mine became deeper. On the dip of the lode a distance of 8100 ft. has been reached, equal to a vertical depth of 5000 ft. It is estimated that at the present rate of extraction the C. & H. conglomerate will be exhausted in 10 to 15 years.

The capacity of the mines may be given at 6000 tons of conglomerate and 2000 tons of amygdaloid ore per day. The mill works 80 to 82% of its actual capacity, and the smelter 60 to 70%. On the Oseola lode, hoisting is only done to the extent of 20% of the capacity, or to the amount of 2000 tons daily. This Oseola lode has only been producing the last four years, and has yielded 20 to 25 million tons of rock, and is now yielding at the rate of 9 to 10 million pounds of copper yearly, but this has not offset the decrease in the yield from conglomerate.

Until 1904 the company mined only the conglomerate lode, one tenth of the output being broken from the Kearsarge and Oseola lodes. Where worked by the company, one third only of the Oseola lode is said to be profitable, and on the Kearsarge no profitable mining has been done. On this latter lode payore runs 17 to 18 lb. per ton. With the increase in depth, and as it proceeded northward the conglomerate has been found to increase in arsenic content.

One billion feet of timber has been put into the workings on the conglomerate lode, that is, the original C. & H. Thirty million feet, board-measure, is being buried annually. This calls for the yield of 1000 to 1500 acres of wood-land, only the larger trees being suited for mine timbers. The amygdaloid lode, on the contrary, needs but little timber—not more than 5% of the conglomerate.

Costs per ton on the amygdaloid Oseola lode for the year ending April 30, 1906, are given as follows:

<table>
<thead>
<tr>

</tbody>
</table>

This total includes general expense, but not taxes.

The company has two adjoining mills, one treating 6000 tons of conglomerate ore daily; the other, 2000 tons of amygdaloid ore.

The loss in copper in treating the amygdaloid was 3.3 lb. out of 24.57 lb. copper per ton, or a loss of 13.4%. In the following year the loss was 3.66 lb. per ton, or 15%, on the same basis.

The product of the mill was divided into:
Barrel work, or pieces not entering the stamp batteries at all, and which had been first picked out.

No. 1, a size taken from under the stamps, and nearly pure copper.

No. 2, the finest size, containing 20 to 24% copper.

The milling cost in 1906 for amygdalediite ore, broken from the Kearsarge and Oseola lodes, was given at 26.31 cents per ton. This figure seems high when compared to that given by the Oseola company, treating the same ore, namely, 16.7e. per ton.

The concentrate from the various mines in the Lake Superior copper region is melted and refined to produce commercial copper, and this product, the result of the first melting, was found to vary in conductivity for the different mines as follows, based on the Mathiesen standard annealed wire:

When copper is of 90% conductivity it will carry no more than 0.04% arsenic, and when the conductivity is as high as 101, the content in arsenic has dropped to 0.0004%. It appears that traces of arsenic do not interfere with the ductility of copper when used for boiler plates or cartridge cases, though it diminishes the conductivity. Oxygen, which existed as sub-oxide of copper in the best Lake copper ten years ago to the extent of 0.10 or 0.12%, is now as low as 0.05 to 0.10%. This would correspond to 0.45 to 0.90% sub-oxide. The American Brass Co. calls for copper of 95% conductivity for casting purposes, and of 99.5% for wire for electrical purposes.

The capacity of the smelting works at Hubbell is 10 million pounds of refined copper per month of 25 days, allowing for the necessary delays incident to the repairing of the furnaces. In 1896 it was worked to 60% capacity.

With reference to the smelting of the mill-products, the 'barrel work' or lump copper, the No. 0, and the No. 1 copper were sufficiently high-grade to be directly melted, the slag removed, and the copper rabbed or poled to produce a refined article of 99.5 to 101% conductivity. The No. 2 'mineral', containing approximately 20% copper, would, upon melting in a reverberatory furnace, yield a small amount of copper, but chiefly slag containing copper. This slag would be broken up and sent to the blast-furnace, there giving a poor slag, say, 1% copper, and 'cupola blocks', a 95% product. This is properly subject to a melt in a reverberatory furnace, where it is rabbed and poled; since it contains 10 to 14 oz. silver, as well as a little arsenic, it is cast into anodes, which are shipped to the Buffalo works of the company for electrolytic treatment. These anodes have a conductivity of 92 to 95%. In all cases the rabbing was carried to the point where the test-button gave a depressed centre, after which poling proceeded until the button showed itself flat on top and, when carefully fractured, a fibrous structure.

According to W. H. Bassett of the American Brass Co., which is one of the largest users of copper in the United States, tests on 55 samples of Lake copper for tensile strength gave 66.141 lb. per sq. in., and a conductivity of 99.85%. Tests on electrolytic copper made on 511 samples on a wire of 0.03 in. diam. for tensile strength, gave 65.259 lb. per sq. in., and for conductivity 100.32%. Tests for ductility showed an elongation of 1.45% for Lake and of 1.56% for electrolytic copper. Finally, on a wire of 0.80 in. diam. it was possible to give the Lake copper 22.2 twists in a length of six inches, while electrolytic withstood 24.8 twists in that length without breaking.

The Skyscraper an American Type.—Whether the American city has been justified in permitting the skyscraper to flourish, or whether the American investor in the end will find the lofty tower and the huge office building a useful and profitable investment, time only can tell; but that the American architect and engineer have been able to meet the opportunity which has given rise to these structures admits of no discussion. Not only has a type of building based on pure utility and special conditions been evolved, but an artistic design and treatment has resulted that today justly earns the admiration of European critics. And in actual construction no less than in design have American ingenuity and engineering skill been manifest. Structural materials—especially steel, terra cotta, and concrete—have been improved, and their use has been developed along scientific lines, so that the construction of a modern skeleton building, with due regard to all elements of safety, can be carried on with a skill and certainty not excelled in any form of structural engineering. And with the experience of large fires and an earthquake to test his work, the engineer of the modern skyscraper surely can say that he, like his building, stands on a firm and safe foundation. —H. T. Wade, in Review of Reviews.

A stream of lava from the volcano Kilauea on June 3, 1840, flowed 11 miles over the island of Hawaii to the sea. "The burning lava, on meeting the waters, was shivered like melted glass into millions of particles, which were thrown up in clouds that darkened the sky and fell like a storm of hail over the surrounding country."

The Rhodesian mineral output for the month of August amounted to £234,543, which is a decrease, compared with the figures of the previous month, to the extent of £7359, though an increase of £23,801 when compared with the corresponding month of last year.
THE RED RIVER, CORNWALL.

Written for the MINING AND SCIENTIFIC PRESS
By Edward Walker.

The condition of the Red river in Cornwall is giving the community a good deal of anxiety at the present time. The bed of the river is becoming so silted with tailing that an extra rainfall causes disastrous floods. The Red river is what an American would call an 'institution', and those who are acquainted with the history of mining are familiar with the question involved. As there must be many of your readers who have only a hazy idea of the problem, the present opportunity seems a good one for recapitulating the facts.

The Red river is a small stream flowing from the high grounds behind Camborne to the sea at Gwithian in St. Ives bay. It is only about 12 miles long, and if its natural current were not supplemented by mine waters it would be nothing more than a thin rivulet. As it is, the waters from the five largest mines in Cornwall, namely, Dolcoath, Grenville, South Crofty, East Pool, and Carn Brea & Tinner's, run into it. I would add in parenthesis that these waters, which are charged with oxidized pyrite, give the river its name. The amount of water passed into it from these sources is not so very great, for the amount of pumping required at these mines is not more than is necessitated by surface requirements at the dressing-works and power-houses. The first four mines mentioned all discharge their tailings into the river. Carn Brea & Tinner's discharges some of its tailing in this way, but owing to the shortness of water is obliged to stack a good deal of the sand. One of the other mines near-by—the Basset, has to cope with more water, and unfortunately its discharge does not go into the Red river but into another watercourse; otherwise the congestion of tailing would not have become so serious.

I estimate that about 300,000 tons of tailing is discharged into the Red river every year from the mines in question. It is no wonder that the course of the river, even if the flow were uninterrupted, should get silted to some extent. It is probable that the bed is now 10 or 12 ft. higher than it was 40 years ago. The course, however, is not uninterrupted, for 10 miles of its length is occupied with one stream-works after another, at which the tin remaining in the tailing is recovered by means of cheap automatic machinery. The average contents of the 300,000 tons discharged at the mines is probably about 40 lb. of tin oxide per ton, and the extraction at the mines is not more than 75%. It is difficult to give the exact content, as no accurate records are kept. The assay of tin ore is a tedious one, and the Cornish managers have never considered it worth the expense systematically to sample the feed and the tailing, contenting themselves with estimating the recoverable tin by means of the vanning shovel. It seems an alarming statement, but I believe that quite 1000 tons of tin oxide goes in the tailing from these mines into the Red river. The mines treat the ore very completely on all sorts of ancient and modern plant, butresses, rag frames, Frue vanners, Willsleys, Bass tables, etc., and when they are quite done with the ore, the stream-works in the Red river re-grind the sand and pass the richer part of the tailing, which has been concentrated in settling-tanks, over rag frames time after time. The rag frame is a sort of inclined-plane buddle, off which the adhering particles are washed every five minutes or so by an automatic discharge of a stronger current of water. After this continuous washing, there still remains tin oxide in the tailing, and on the beach at Gwithian there is a fringe of concentrate always worth collecting.

The question arises: How is it that the recovery of tin oxide is so imperfect? For one thing, the grade of the ore is so low that the small proportion of tin oxide is apt to be swept along by the greatly preponderating quantity of gangue. Taking 40 lb. as the contents of the ore, this is only 2% of tin oxide. A second reason is to be found in the physical characteristics of tin oxide. Though much heavier than the gangue, it is so 'slippery' that it does not readily adhere to the surfaces of the concentrators. It has no metallic lustre and is easily wet. The tin oxide is finely disseminated in the ores and crushing to 30 mesh is necessary, and the pulp is in the form of fine sand and slime. The 'fine tin oxide does not float away like friable pyrite, but is not easily brought into contact with the tables.

Every time the tailing is sent over a rag frame, a very small proportion is caught, perhaps not 5% of the contents. This explains how it is that one stream-tin works after another can make operations pay. The question may be asked, Why do not the mines or upper stream-works pass the tailing over rag frames more than once? The answer is that they have no further surface space at their disposal, and that there is no alternative but to spread the continual dressing operations right down the length of the river.

As I have remarked already, the present situation on the Red river is giving trouble owing to the filling of the bed. The danger comes when there is a sudden rainfall after a drought. As a rule the amount of water other than that discharged by the mines is not great. When severe rains come, the river is filled rapidly and it overflows its banks, causing great inconvenience to the agricultural interests. The landowners and the public authorities are giving the matter their attention.
COMPANY REPORTS.

SIMMER & JACK.

This is one of the mines, and the largest, controlled by the Consolidated Gold Fields of South Africa. The Simmer & Jack is, however, operated by a subsidiary company named the Simmer and Jack Proprietary Mines, Ltd., having a capital of £2,000,000. The report for the fiscal year ending June 30, 1908, states that the mill of 320 stamps crushed 785,310 tons, showing an average duty of 7 tons per stamp. The yield was augmented from several sources, thus:

<table>
<thead>
<tr>
<th>Source</th>
<th>Tons</th>
<th>Oz.</th>
<th>Value per ton.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Battery</td>
<td>785,310</td>
<td>165,526</td>
<td>£696,524</td>
</tr>
<tr>
<td>Tube-mills</td>
<td>332,653</td>
<td>43,209</td>
<td>184,813</td>
</tr>
<tr>
<td>Sand</td>
<td>54,727</td>
<td>75,457</td>
<td>187,260</td>
</tr>
<tr>
<td>Slime</td>
<td>237,372</td>
<td>16,343</td>
<td>85,734</td>
</tr>
</tbody>
</table>

Thus it is seen that 785,310 tons of material were treated, yielding £1,267,411, or 7.67 dwt. per ton. The total operating expenditure was £896,907, or 16s. 2d. per ton crushed. The working profits were £281,915 and the net balance to revenue was £601,067 15s. 4d. Dividends aggregating £600,000 were paid, leaving a balance on hand of £197,947, as compared to a previous balance of £243,239. The ore reserves are estimated at 1,902,000 tons, averaging 7.65 dwt. per ton. In addition, 134,900 tons are partly developed. During the year 333,411 tons were hoisted, of which 116,456, or 15.59%, was separated, by sorting, before milling. During the year some 4000 Chinese laborers were replaced by Afrikaners, and this entailed a heavy expenditure. It is believed that the example of efficiency set by the Chinese, now being repatriated, has had an excellent effect on the Kaffirs. The consulting engineer is H. H. Webb, the general manager is C. D. Leslie, and the superintending engineer is Leslie Simson.

The Consolidated Gold Fields of South Africa report for the year ending June 30, 1908, shows that the profit won from subsidiary companies was £562,798, on a capital of £2,000,000 in ordinary shares and £1,250,000 in preference shares. Of the profit, £465,260 is available for dividend.

GLOBE & PHOENIX, RHODESIA.

The directors of the Globe & Phoenix Gold Mining Co., in their interim report for the half-year ended June 30, 1908, show a material improvement in tonnage and value of ore as compared with the end of 1907, the respective figures for ore reserves being 107,309, against 132,403 tons, worth £526,917 and £315,513. On July 8 last an interim dividend of one shilling per share was paid, and the board has now declared a second interim dividend of one shilling per share, free of income tax, payable on October 8.

H. A. Piper, one of the consulting engineers of the company, stated that development was confined to the Phoenix mine, the Globe mine being now completely closed down and worked out. The advance for the half-year amounted to £3621 ft., as follows: permanent work 44 ft., development work 3322 ft., dead work 45 ft., bringing the total footage in the mines to 37,336 ft. The main shaft had reached a depth of 2165 ft. The vein at the bottom averaged 22.1 dwt. over a width of 31.3 in. The grade of the ore has materially improved in depth, the increase from the fourteenth level downward being most marked. The anthracite present will continue to decrease the extraction until the sorting plant, expected to be running before the end of the year, is working; meantime the only serious loss is in the sandplant, but the sand tailing is being accumulated for future treatment. The slime extraction is good. At present the slime is being stored and allowed to oxidize. The accumulated slime only has been traced. Although this meant re-handling, the extra cost is more than compensated for by the improved extraction. Details of the different departments Mr. Piper gives as follows:

- **MILL**
  - Forty stamps, 169 days 23 hr. 50 min. Ore, crushed, 37,546 tons.
  - Duty per stamp per dwt., 5.82 tons.
  - Extraction per ton in fine gold, 8.34 dwt.
  - Average tailing assay, 3.92 dwt.
  - Profits on milling, £3,510 17s. 2d.

- **CYANIDE PLANT**
  - Sand treated, 25,644 tons.
  - Yield in fine gold, 2225.07 oz.
  - Assay value of charges, 4.12 dwt.
  - Assay value of residue, 2.20 dwt.
  - Actual extraction, 42.12%.
  - Cyanide consumption, 0.86 lb. per ton.
  - Zinc consumption, 0.17 lb. per ton.
  - Sulphuric acid consumption, 0.21 lb. per ton.
  - Cost per ton treated, 3s. 2d.
  - Profit for six months, £5269 6s. 4d.

- **SLIME PLANT**
  - Accumulated slime treated, 7175 tons.
  - Current slime treated, 3577 tons.
  - Yield in fine gold, 973.05 oz.
  - Cyanide consumption per ton, 0.68 lb.
  - Zinc consumption per ton, 0.23 lb.
  - Sulphuric acid consumption per ton, 0.19 lb.
  - Profit for six months, £1665 5s. 7d.

Concluding, Mr. Piper says that “the increase in ore reserves and values is encouraging, and is due entirely to the enrichment in the deeper levels; indications point to the fact that the vein is narrower with depth, which, taken in conjunction with the contemplated increase in sorting, will necessitate more active development than hitherto, especially now that the Globe mine is closed: the gold extraction and milling grade should, however, improve. I would emphasize the fact that at the depth at which the mine is working, namely, 2300 ft., it is one of the deep quartz mines of the world; and the continued reduction in working costs under these conditions should be considered satisfactory.

The figures were striking, in view of the output raised in some quarters against the Government’s action in ordering an improved scale of diet during the latter portion of 1907.

The details of costs per ton were as follows, on a total of 37,546 tons:

- **Mine development redemption**
  - 0     | 4     | 0.60  |

- **Cyanide per ton milled (including maint.)**
  - 0     | 2     | 2.05  |

- **Slime (Including maintenance)**
  - 0     | 6     | 3.36  |

- **Total**
  - 0     | 6     | 10.58 |

The cost per ton of sand treated was 3s. 2d., as against 3s. 2d. last year. The cost per ton of slime treated was 4s. 4.14d. Waste sorted out, 2456 tons, having an average value of 0.78 dwt. The gross value of the ore treated was £2 2s. 1d., this, therefore, leaving a profit of 15s. 2d. per ton, or an aggregate of £8,475 9s. 1d., excluding depreciation, London office expenses, and other charges. Since the commencement of milling operations the mines have produced £1,351,590, from which it has been obtained a net profit of £391,919.
MINING AND METALLURGICAL PATENTS.
Specially reported for the MINING AND SCIENTIFIC PRESS.

MINE-ROOF SUPPORT.—Frederick C. Kelchhey, Uniontown, Pennsylvania.

A device of the class described, comprising a pair of standards, a horizontal member, having notches engaged by said standards, said standards being inclined inwardly, inclined braces extending from the upper part of said standards to a point near the centre of said horizontal member, struts adapted to encircle the upper portions of said standards and the ends of the horizontal member, said struts being formed with projections at their lower ends, said projections being adapted to support the inclined braces at the point where they meet the standards.

PUMP FOR MINE-SHAFTS.—No. 904,579. Richard Heidecke and Otto Lellau, Neuhof, near Fulda, Germany.

A pump for sinking mine shafts, comprising in combination with the pump and its suction pipe, a flexible armored connection between both consisting of a flexible tube, flanges at both ends of said tube to connect the latter to said pump and suction pipe respectively, a series of divided U-rings disposed so as to surround said tube and to have their webs alternately placed outward and inward, and stays to rigidly connect said rings, for the purpose set forth.

A rock-drill of the nature specified comprising in combination a holder and a detachable bit having a plurality of substantially tangential cutting edges and a circular cutting edge at the centre, and means for detachably securing the bit to the holder.

In an apparatus of the class described, the combination of a pair of main rails; a pair of dump-tracks which extend alongside said rails and are provided at one end with switch-pieces that extend toward said rails, the latter continuing beyond said switch-pieces in both directions substantially parallel to said dump-tracks; and a skip-car provided with two pairs of wheels, the tread of one of said pairs of wheels being greater than the tread of the other of said pairs and the interval between said switch-pieces being greater than the interval between said main rails: whereby the wheels of narrow tread continue on said main rails past said switch-pieces and between said rails and dump-tracks, while the wheels of wide tread engage said switch-pieces and ride along the outside of said dump-tracks.

CRUSHER AND PULVERIZER.—No. 904,909. Milton F. Williams, St. Louis, Missouri.

A crusher or pulverizer provided with beaters or hammers, a pivotally mounted grinding surface and a rotatable breaker plate, and means for simultaneously adjusting said grinding surface and rotatable breaker plate relatively to the hammers; substantially as described.

In a device of the kind described a pedestal, a sliding oil cup carried by said pedestal, said cup having a bearing for an axle, and bosses formed on a side of the pedestal and upon opposite sides of the oil cup, said pedestal having reservoirs formed therein and being provided with passages leading through said bosses to said reservoirs and from said reservoirs to opposite sides of the oil cup, respectively, the bosses overhanging the entrance to the passages leading through them.

In an apparatus for the purpose stated the combination with a hinged door and a railway track, of a door operating member arranged adjacent to one of the rails of said track and having its upper edge normally above said track rail, said member being provided with a series of graduated slots, a trip, a trip bar, said bar having a series of graduated slots, rock arms supporting said member and trip bar and engaging said slots, operative means for said door, and connection between said member and said door operative means.
Gasoline Rock-Drill.

A gasoline rock-drill has been invented and built by L. L. Scott, a manufacturer of gas engines, at Joplin, Mo. The double-acting piston type is illustrated in this article. The engines on all of these drills work on the two-cycle principle.

From experience, the requirements for a practical piston gasoline rock-drill were found to be as follows: Must receive an impulse on every up and down stroke. A powerful up-stroke is required for drilling deep down holes from 10 to 30 ft. deep, as there is a great weight in the steel to lift, also a tendency for the steel to hang in the hole. Working parts must be entirely enclosed and water-tight. Must be light enough so that two men can handle same. Piston must be a solid piece of steel and yieldingly connected to a crank-shaft (free piston impossible). Must be free from all valves, gears, push-rods, cams, and other delicate parts that would not stand up under the hard usage to which it is inevitably subjected.

The drill illustrated was built with these points in view. It is compact and weighs 174 lb. It will drill three inches per minute in hard granite and will consume ½ gal. gasoline in 15 min. if doing hard drilling. This type of drill is adapted for holes from 10 to 30 ft. deep, while the small hammer type will drill shallow holes equally as fast with half the amount of gasoline.

Briefly, the drill is a unique type of double-acting, two-cycle gas engine. The charges are drawn in at the upper and lower ends of the drill through ports, are compressed and passed to the central part of the drill, where they are exploded alternately (one for the up and the other for the down stroke), and act on the inner faces of the piston. The drill-rod has a swivel connection with the piston and is free to rotate independent of the piston. The rotating device is placed in the lower charge receiving chamber. The crank-shaft is cushioned so that there is no jar on the bearings when the bit strikes the rock. The pistons are acted on by 300 lb. explosive pressure, and are practically free from the crank-shaft when the bit strikes the rock. This gives the result of a free piston, at the same time the crank acts as a guide to insure the proper port opening, keeps the piston from knocking out a head if a pocket is struck in the rock, and is a means of starting the drill. The piston has the usual U bolt-chuck for holding the steel. All parts are oiled automatically by oil that is mixed with the gasoline and drawn in with each suction of the engine. The drill as a whole permits a rigid construction and is a model of simplicity. Common rock-drill mountings are used to support the drill, in connection with the usual feed-screw.

Where the drill is used underground the exhaust is either carried through a steam hose to a waste-pipe leading to the mouth of the shaft or tunnel, or is run through a special valve into a chemical solution and absorbed thereby. The constant suction of the intake of the engine draws air to the place where the drill is operating and is a means of furnishing ventilation.

Publications Received.

Any of the books reviewed or mentioned in these columns are for sale or procurable from the MINING AND SCIENTIFIC PRESS.

The author frankly states that the information is compiled from various publications, and the practice of the best engineers is fully taken into account. The book describes many 'short cuts' and 'kinks' used in underground surveying, originating through the experience of practical men. The chapter on map making is good, and the entire volume contains much matter valuable for the experienced surveyor as well as the beginner. The methods described are essentially American.

This is a compact account of the industrial development of electro-metallurgy, prepared by a recognized authority and written in language that everybody can understand. Any technical terms used by the author are explained in a glossary at the end of the volume. We can commend this book as useful and trustworthy.

Economic Geology of New Mexico. By Fayette A. Jones. Published by the authority of the New Mexico Bureau of Immigration. Albuquerque, New Mexico.

Catalogues Received.

The American Steam Gauge & Valve Mfg. Co., Boston, has recently issued a catalogue of its extensive line of valves.

The Western Electric Co. is distributing a small folder showing views of its cable manufacturing plant. It also sets forth the advantages of cables for telephone service.

The Stromberg-Carlson Telephone Mfg. Co., Rochester, New York, is distributing several little booklets setting forth the advantages of the key type of intercommunicating telephones.

The Hammond Iron Works, Warren, Pa., reports a steadily increasing volume of business. The company has recently opened a branch office in Mexico City, which is in charge of Francis E. Pratt.

The Westinghouse Electric & Mfg. Co. has just issued its 1909 vest pocket diary, which, in addition to the diary feature, contains an immense mass of engineering data, formula, maps, and miscellaneous information.

EDITORIAL.

**NIPISSING** is claimed to be producing silver at a cost of 11 cents per ounce, but the president of the Nipissing Mines Company does not hold his operations responsible for the drop in silver. An abnormally small demand for silver in the arts and a slackening of demand from India and China are the principal factors; another is the large proportion of silver produced as a mere incident in the extraction of the base metals.

**NOWSLIDES** usually start in the spring, but occasionally the early snows are piled so as to form avalanches. From Silvertown, in Colorado, comes news of several fatalities. This region, known as the San Juan, has long been lamentably celebrated for snowslides, and many is the poor miner that has been suddenly buried in the mountains that look down upon Silvertown, Ouray, Rico, and Telluride. The railroads have been blocked by snow and there is promise of a severe winter.

On another page we publish an abstract from the excellent paper by Mr. Reginald E. Hore on the ‘Origin of Cobalt-Silver Ores of Ontario,’ with special reference to the district of Cobalt. The revival of interest in this part of Canada seems warranted by the better returns from the mines; and the discovery of new silver-producing areas near Gowganda Lake and elsewhere in northern Ontario gives promise of an extension of activity in a part of the world the geology of which presents many remarkable features.

From Johannesburg our correspondent sends a particularly interesting letter this week. In the course of it he refers to the failure of the Gordon drill, which has not been able to confirm the excellent results obtained in the stope-drill competition. It is the old story of trials that were not properly indicative, because conditions were not representative. But the effect of the competition in drill-making is excellent, and we shall expect to see the Gordon drill modified to suit working conditions, while other drills also will profit from the records of experience.

The Australian Mining Standard, published by Mr. Critchley Parker, celebrates its 20th anniversary by issuing a number that is especially good, both as to typography and contents. We congratulate out antipodean contemporary. The twenty years of its life cover a stirring period in the history of Australian mining, including the birth and development of the gold mines of Western Australia, the growth of a varied mineral industry in New South Wales, the decadence of Ballarat and Bendigo, the production of copper as well as gold at Mount Morgan, the treatment of the dumps at Broken Hill, the
making of big mines at Mt. Lyell in Tasmania, the Waihi in New Zealand, the Mount Boppy in Queensland. Through all these vicissitudes the Mining Standard has held its pennant aloft; we salute!

Philadelphia has long been accepted as typifying what is slow but sure. Apparently the technical societies of that fine city partake the character of their environment. Thus the Journal of the Franklin Institute publishes a page recounting the mineral production of the United States in 1906; this will be found in the bulletin of the Institute dated December, 1908. These figures ought to be reliable.

Our local contemporaries are now publishing a pseudo-scientific rhapsody concerning the growth of gold. Thus The Evening Scream says that "miners on returning to worked-out diggings or abandoned shafts have often discovered rich stores of gold in places where the vein had previously been exhausted." Thereupon The Morning Hotel quotes "practical miners" living at the nearest hotel, distinguished experts long since extinguished, and professors who profess to be professors, all of whom assert that in some queer alchemic way gold will grow if you give it a chance. This is a good example of newspaper science, like children who have been given some simple lesson in chemistry, they build weird superstructures of supposition worthy of the nursery. Some tired space-writer has been told that gold is precipitated from solution; that it is believed to occur dissolved, in underground waters, and that the timbers of old workings have actually been found slightly enriched by gold thus precipitated from solution through the reducing action of organic matter. That is all.

Merchants in San Francisco and business men in California are indignant at the proposal of the Union Pacific, or Harriman, railroad to increase the freight toll on merchandise to or from California common points. We hope they will continue to be indignant and translate their feelings into vigorous action. This is no time for the railroad company to levy increased charges; the threat to do so indicates the irresponsibility of those in control. In the year 1907 the Union Pacific Railroad Company earned $87,627,000 gross and $47,053,000 net as compared to $77,619,000 and $42,349,000, respectively, in 1906. Thus even the panic did not stop the wonderful expansion of business that has carried this railroad enterprise since 1897, when the company was re-organized. Even the fixed charges were only $1,926,000 per mile in 1907 as compared to $2,600,000 in 1904. The surplus was $36,178,000, the largest in the company's history. In 1908 the gross earnings have continued to grow, and the entailing of operating expenses has been such that the ratio is 45 per cent, as against 60 per cent in 1907. The railroad is extraordinarily prosperous, having the control, political and industrial, of a vast region, rich in natural resources. The present rate of dividends is 10 per cent on the common stock and 4 per cent on the preferred. Owing to this showing the stock has been advanced to the highest figures on record, the common selling for $185 and the preferred for $89 per share. The people that pay tribute to the railroad have suffered severely from a period of industrial depression while the railroad company has enriched at an unheard of rate. And this is the time chosen for the levying of an increased impost on the traffic of the West! It is another example of the colossal impudence of Mr. E. H. Harriman.

Congratulations to the Geological Survey on escape from a great disaster! On the night of December 16 a fire broke out in the Hooe Building, at 1324 F street, Washington, and imperiled records of the greatest value. The fire was detected by the night watchman; apparently it started in the elevator shaft on the sixth floor and spread to the fifth floor, where the water supply division has headquarters. Here records, chiefly maps and photographs, were burned. On the floor above is the collection of photographs that form so attractive a feature of the Survey reports; these, we much regret to say, were destroyed. But the library was uninjured and the statistical records of the Mineral Resources division, on the second and third floors, suffered no harm. At the time of the fire the Director, Mr. George Otis Smith, and the chief of the Technological Branch, Mr. J. A. Holmes, happened to be in the building; from press reports we gather that both of these gentlemen did excellent work in saving valuable papers and assisting the firemen. Whether Mr. Smith and Mr. Holmes were having a warm discussion, and whether the anticipated friction between the Survey and the proposed Mining Bureau developed enough heat to set the building on fire, is not related. We rejoice in the escape from a calamity.

From reports of proceedings on the Boston and New York exchanges it appears that stocks have been depressed by unloading of large blocks of shares by leading operators. A sapient commentator in the daily press says: "The exact meaning of the present liquidation is difficult to determine." The humor of it! It is the same old game, young man; the same old game that has been played time out of mind. First optimistic talk and racy prophecies of expanding business, then boosting of stocks to a level that even the complete fulfillment of expectations would not warrant, then a buying movement by the same old guileless public, with gentle unloading at top prices on the part of the 'insiders,' namely, the comparatively small group of clever manipulators to whom the Stock Exchange is a veritable mint. When the election of Taft promised restoration of confidence, when the blight on business seemed about to be lifted, when the invincible progress of this great country seemed assured—and when all these factors had been liberally discounted by the knowing ones—then the public, 'the man on the street,' the widows and the orphans, the sheep and the 'lambs' that follow the pied pipers of Wall
Street, all rushed to their brokers and bought stocks. Then the ‘big fellows’ who sell with the ‘boom’ and buy with the ‘bust,’ began to dole out their stocks to the simple and greedy from the Atlantic to the Pacific, and even on the other side of the Atlantic. The process is not mysterious and it is not new, although the scribes of the daily press try to make it appear wonderful.

**Railroads in Western Mexico.**

The first railroad from the Mexican plateau to the Pacific Ocean was formally opened to traffic on December 12 by President Diaz, in the presence of a distinguished company of representative men. This pioneer road across the Sierra Madre is a branch of the Mexican Central from Guadalajara to Manzanillo, a port in the State of Colima, 250 miles west-northwest from Acapulco. Its completion is a notable event, as are all steps for the utilization of natural resources, and it justified the elaborate celebration that was further honored by the presence of the great leader of Mexican progress. Although it may not appeal to the world as did the opening of the Tehuantepec line, it is of greater practical importance. The saving in world-freight by the trans-isthmian road in ten years will not equal the increase in property-value of a single year which the development of the West Coast of Mexico will occasion. This region has remained virgin to agriculture and commerce. It was not the natural obstacles to railway construction that retarded the Pacific zone. Although the canyons were deep, and the mountains rugged, the difficulties were not insuperable. The West Coast was neglected because it was not then needed. But the time is now ripe. Land-hunger is leading to the development of the rich deltas that stretch for hundreds of miles from Manzanillo to Guaymas. The Southern Pacific Company is building a great railroad, now almost completed, establishing communication between the main line of the trans-continental system in Arizona, by way of Guaymas, Culiacán, and Mazatlán, to Guadalajara. Thus will a second trans-sierra route be opened within a year, and other roads will follow. The Kansas City, Mexico & Orient Railway lacks only the mountain division in Chihuahua to afford another, which will be the shortest cut from New York to tide-water on the Pacific. At the western terminus is the deep harbor of Topolobampo, sheltered by converging mountains. From this port the line is open to traffic as far as Choix, an important copper district. The route across the Sierra lies close to such well known mines as Lurin de Oro, Batopilas, Concheño, and Pinos Altos. The Miller and Sibley mines at Topia, said to have developed the largest known body of lead-ore in America, will shortly call for rail connection westward to the new road of the Southern Pacific Company, and the purchase by the Standard Oil Company of enormous pine-reserves on the plateau, stretching eastward from Topia, will necessitate extension of the line to the Mexican International at Tepuhuanes. Thus will be completed the work planned and surveyed by Mr. E. P. North, the pioneer railroad builder on the Pa-

cifie seaboard of Mexico, 30 years ago. Because of isolation, these western States have only begun the development of their mineral resources: many mines along the great escarpment that forms the seaward front of the Sierra Madre—El Tajo, Guadalupé de los Reyes, San José de Grieria, to name a few—have produced millions, and while so much has been won in the face of almost throttling difficulties, more is to be expected when highways are created. The opening of the railroad from Guadalajara to Manzanillo marks the offering of a new field to industrial development.

**Mining Law in Alaska.**

The ability of one person to stake an unlimited number of mining claims is a hindrance to the development of Alaska. A prospector can go up a creek and stake for himself and his friends as many claims as he likes, provided he makes a discovery on each claim of 20 acres; or, he can stake an ‘association’ claim of 160 acres in the name of eight men and with but one discovery. The use of the other men’s names on the notice of location is often a subterfuge to avoid the operation of a district regulation limiting an individual to a single claim; frequently the names are used without authorization, and the presumption that a person has authorized an act that is for his benefit operates to validate the action taken in his behalf. The practical result is that the country is blanketed with such locations, made, not by bona fide prospectors, but by speculators. Judge Wickersham comments on the situation, in one of his opinions, as follows: ‘The greatest evil in the administration of the mining laws in Alaska is the habit of the shiftless and grasping in staking and recording mining claims, generally by power of attorney, whereby one person often acquires a claim to a large area of supposed mineral land, and excludes the willing miner from working it and developing the resources of the territory. Since the threat of a lawsuit lurks behind each of these pretended locations, the prospector generally passes it by, and thus the speculative locator controls the property.’

On the Totanlanka, two years ago, a party of five men staked 16,000 acres. In the Bonnfield country, a party of four located 27,000 acres. This is a gross perversion of the law, of course. Last year two men went from Hot Springs to Sullivan creek and located four miles for a width of 1000 ft. in association claims, using the names of people residing in the neighboring district. Then they notified these people that they had been ‘staked’ and asked them for $50 or $100, on account; if they paid, all was well; if they refused, the name on the location notice was erased, and another was inscribed. Thus the same claim was sold several times over, and then the perpetrators skipped, remaining away until the affair had been forgotten. In Judge Wickersham’s court in 1906, when the validity of a ‘nukek discovery’ was in dispute, a witness testified that he had walked from Fairbanks to Cripple creek, a distance of eight miles, and had then staked 10 claims of 20 acres.
each, placed upper and lower centres and four corner posts, blazed his boundary lines, made a ‘discovery’ with a pie plate on each of the 10 claims, and he did this (so he testified under oath) on April 15, when the snow lay two feet deep in the woods. It is estimated that he walked 42 miles, to say nothing of the time spent in preparing the notices, and so forth. Bedrock was 165 feet below the surface, and 135 feet of ‘muck’ covered the gravel! Comment is superfluous.

‘Discovery’ is the feature of the law that is most abused. Without a valid discovery, a location ‘would be justly treated as a mere speculative proceeding, and would not itself initiate any right,’ in the language of the United States Supreme Court. And yet in Alaska, where the pay-gravel is buried beneath many feet of frozen ‘muck,’ claims are staked by the wholesale without any attempt to penetrate through material that is not mineral-bearing. Such claims are invalid, and after the lapse of a reasonable time the courts will not protect the locator for the purpose of allowing him to make an actual discovery. Another locator may then step in and perfect an adverse claim by making a sufficient discovery. The courts have also held that the mere presence of gold ‘colors’ on or near the surface, unless connected in some way with the deeper lying and valuable deposit, does not in itself constitute a valid discovery. Of necessity, a determination of each case depends upon its own facts.

The effect of these practices is to keep the bona fide prospector off the ground. He may work ever so hard and explore ever so energetically, only to find himself in a lawsuit, his ground having been staked by an itinerant and haphazard speculator. If some restriction were placed upon the power of attorney, and each locator were compelled to make a valid discovery and do the required amount of assessment work, the golden regions of the North would undergo rapid development.

The performance of annual labor, or so-called ‘assessment work,’ to the extent of $100 for each claim is also frequently evaded or perfunctorily performed. To comply with the law, such work must actually benefit the location for which it is performed, and it must facilitate the extraction of mineral therefrom. In Alaska a shaft 10 or 12 feet deep in ‘muck’ is considered the equivalent of $100 in value, but usually such an opening is filled by thawing in one season and the work wasted. There are many who feel that the amount of work required should be increased. Under the existing law the ground may be ‘tied up’ or sequestered for two years without any real prospecting. This is a long time to postpone development, and it would seem to be wise to require a certain amount of ‘location work,’ as in Nevada and other mining States.

We have called attention to these serious hindrances to legitimate mining in Alaska, not so much with the idea of proposing alterations of the existing laws as to point out wherein the real trouble lies. The existing mining laws have been in operation for many years, and while they are by no means ideal, yet their chief value lies in affording security of title. To trifle with the laws and seek legislation as a remedy for every real or imaginary evil will only tend to produce confusion, insecurity of title, and additional opportunity for litigation. The grievance lies not so much against the laws as they exist as against their evasion. The remedy is not to be found in their alteration, but rather in their enforcement. To quote again from the opinion above referred to: ‘One of the cures for this speculative reservation of mineral land is presented in this case. The Court ought not to assist a mere staker, after he has had a reasonable opportunity and time within which to do the necessary work to make a discovery on his claim, by restraining another prospector who seeks to go upon the land and comply with the spirit of the law by mining for gold thereon.’ This is not the first time in history that these evils have been encountered. By referring to an authority on the subject of tin mining in Devon and Cornwall, we find that the ‘laxity of stannary law in respect to the enforcement of the required amount of annual labor gave many opportunities for the abuse of the right of bounding (staking) in the Middle Ages, and in 1786 all Dartmoor, comprising 50,000 acres, was claimed by a single prospector.’ The same abuses spring up in every new mining region. In the case of Alaska, the wild nature of the country, the severity of the winter, the limited population, the great distances and hardships to be overcome in traveling, and the consequent inaccessibility of the Courts to certain parts of the country, all tend to make difficult the strict administration of the law, whether it be civil or criminal. It is little wonder that lawlessness is in evidence in places, and hope for the improvement of these conditions in the future lies in the steady development of the country and the increase of a law-abiding population, rather than in a resort to legislation with the idea of improving existing laws. To compel a locator to make a bona fide discovery, or to go into possession and work till he effects a discovery, and to enforce the performance of the requisite labor on each claim annually, will do more to check the indiscriminate and wholesale locating of the mineral lands of the public domain by speculators than any new mining code that could be devised.

The Write-Up.

The exploitation of a manufactured product in the guise of reading matter is called a ‘write-up.’ It is not a literary word and it does not represent literature; it is the exponent of a commercial idea in the guise of scientific or technical information. In the daily press you find yourself reading a paragraph that begins with a seductive reference to the ‘grandeur that was Greece or the glory that was Rome’ and ends by recommending Smokey’s soap. In the financial press you become absorbed in a picturesque account of South African mining only to discover that you have been inveigled into a consideration of the opportunity for sudden wealth presented by the shares of the Great Bullion Extended Mining Co. in southern Nevada. In a technical paper you plunge into a turbid description of pumps and
their work in mines, to find that the purpose of the article is to recommend the Jones centrifugal pump manufactured by the Jones Co. of Jonesville, Tennessee. If you are good natured, not too busy, and possessed of a sense of humor, you laugh at yourself as the victim of a practical joke; if, however, your liver is sluggish, or you are a busy man, or do not appreciate foolery, you kick yourself for being deceived and there is developed a longing to express your sentiments to the responsible editor. Undoubtedly, the 'write-up' is in the nature of an impertinence. But besides the cruder forms of this insidious method of gaining publicity without payment, there are unaffected descriptions of manufactured products that appear in trade and technical papers.

Thus the write-up becomes a specious indorsement of one advertiser's wares at the expense of the other advertisers, and eventually it is to the detriment even of the favored individual. For it is obvious that if a 'write-up' is not as trustworthy as matter coming from an unprejudiced source, then it lessens the interest of the reading portion of the paper and renders the advertising less valuable. There is no escape from this conclusion. The representative of a machinery firm brings a description of his works, with a photograph of the establishment, and wants it published as reading matter. The sight of it in the paper may gratify the members of that particular firm, but it is certain that it is of value to no one else, for the products of manufacture do not depend for their excellence on the appearance of the building in which they are made. Moreover, the insertion of such an article is not fair, for the advertiser is simply asking for so much gratuitous advertising in a part of the paper where he thinks he may get exceptional publicity. The reader is annoyed, for the 'write-up' is not of interest to him; he does not rate Smith's pumps by the look of Smith's factory.

It comes to this, that anything which lessens the interest of the reading pages tends to hinder the purpose of the advertising; protect the reader and you safeguard the advertiser, for no one that has become annoyed or displeased with the reading matter is likely to spend much time over the advertisements; on the contrary, it is the satisfactory character of the articles that will cause a reader to hold a paper in his hands long enough to turn over the pages of advertisements.

But we shall be told that there are write-ups and write-ups; that what we have said may apply to certain forms of this method, but it does an injustice to the skillful write-up, which gives reliable information while incidentally fulfilling another purpose. This is a matter of opinion. Even the best of the stuff sent broadcast by the publicity bureaus of manufacturing companies is prejudiced, among the facts lurk fallacies, between the scientific data are sandwiched the exaggerations of a salesman. It may be a long way from the fervid rot of a corn doctor to the pseudo-scientific literature of a publicity manager, but there is every gradation between them and they are tainted by the same fatal defect. It is the editor's duty to protect his reader; in so doing he advances the best interests of the advertiser, for by such methods the advertiser is given the best opportunity to win the attention of the reader. For this reason the signed article that masquerades as an independent statement, while really the puff of an advertiser, is particularly objectionable. Not content with self-laudatory paragraphs, some manufacturing firms employ technical men to write articles for publication, in which the principles underlying certain types of machinery are specially advocated, so as to prepare the way for the reception of a recommendation of the machines themselves. Of course, there is no reason why the inventor or the manufacturer of a machine should not tell the truth in an interesting way, and it happens often that information concerning processes and devices can be obtained only from such sources. In that case, the position of the author should be fraudulently stated; it certainly would be deemed a courtesy to the reader and would tend to inspire confidence. Any feature of the reading pages that wins the confidence or commands the respect of the reader, by so much increases the value of the service given to the advertiser.

Is this Utopian and impracticable? We trust not. It is sound business, not poetry. The practice of recommending mining stocks and puffing companies in the editorial columns because they advertise their prospectuses on another page has died out in America, that is, among journals of any standing. In London the mining papers are still subventioned in various ways: the mining company pays for an account of its meeting, for the publication of reports, for reprints of the speech made by its chairman, and for sundry other ways in which it gets favorable publicity; the papers distribute praise or blame, or maintain an ominous silence, according to the amount of advertising taken with them. Paid matter appears in the heart of the reading pages, the right hand watches the left, the business department and the editorial are partners in a sordid business. And what is the result? The advertising pages have scarcely any value. Why? Because the reading matter is unreliable. There you have it. In America the leading mining journals do not insert paid matter in their reading pages, and the only blemish is the 'write-up,' which is a sop to Cerberus, the donation of extra publicity gratuitously to those who advertise, or are expected to advertise, in the paper. This reminds us of a petty form of 'graft' operated in connection with write-ups. A firm that does not advertise with you will send a write-up 'because it is interesting' and it will have the cheek to ask you to publish it to the end that its products may be advertised free. This does an injustice to the advertiser that pays. The excuse to be made for the 'write-up' is that it is a courtesy to a client, a concession to one with whom you are doing mutually profitable and honorable business, therefore when a non-advertiser asks for advertising space in your reading pages he exhibits monumental effrontery. Your reader does not even have the satisfaction of turning to the advertising pages for further information. A young man obtained a testimonial as to his ability from his own mother. That is the 'write-up' in its simplest form—interesting to the family!
BY THE WAY.

At the recent meeting of the British Association for the Advancement of Science, Professor John Joly gave an address on 'Uranium and Geology'. He said, in part:

In our day but little time elapses between the discovery and its application. Our starting-point is as recent as the year 1903, when Paul Curie and Labord showed experimentally that radium steadily maintains its temperature above its surroundings. As in the case of many other momentous discoveries, prediction and even calculation had preceded it. Rutherford and McChung, two years before the date of the experiment, had calculated the heat equivalent of the ionization effected by uranium, radium, and thorium. Even at this date (1903) there was much to go upon, and ideas as to the cosmic influence of radio-activity were not slow in spreading.

I am sure that but few among those whom I am addressing have seen a thermometer rising under the influence of a few centigrams of a radium salt; but for those who pay due respect to the principles of thermodynamics, the mere fact that at any moment the gold leaves of the electroscope may be set in motion by a trace of radium, or, better, still, the perpetual motion of Strutt's 'radium clock', is all that is required as demonstration of the ceaseless outflow of energy attending the events proceeding within the atomic systems.

Although the term 'ceaseless' is justified in comparison with our own span of existence, the radium clock will, in point of fact, run down, and the heat outflow gradually diminish. Next year there will be less energy forthcoming to drive the clock, and less heat given off by the radium by about one three-thousandth part of what now are evolved. As geologists accustomed to deal with millions of years, we must conclude that these actions, so far from being ceaseless, are ephemeral indeed, and that if importance is to be ascribed to radium as a geological agent, we must seek to find if the radium now perishing off the earth is not made good by some more enduringly active substance.

That uranium is the primary source of supply can not be regarded as a matter of inference only. The recent discovery of ionium by Boltwood serves to link uranium and radium, and explains why it was that those who sought for radium as the immediate offspring of uranium found the latter apparently unproductive, the actual relation of uranium to radium being that of grandparent. But even were we without this connected knowledge, the fact of the invariable occurrence in nature of these elements, not only in association but in a quantitative relationship, can only be explained on a genetic connection between the two. This evidence, mainly due to the work of Boltwood, when examined in detail, becomes overwhelmingly convincing.

Thus it is to uranium that we look for the continuance of the supplies of radium. In it we find an all but eternal source. The fraction of this substance which decays each year, or, rather, is transformed to a lower atomic weight, is measured in tens of thousands of millions so that the uranium of the earth one hundred million years ago was hardly more than one per cent greater in mass than it is today.

As radio-active investigations became more refined and extended, it was discovered that radium was widely diffused over the earth. The emanation of it was obtained from the atmosphere, from the soil, from caves. It was extracted from well waters. Radium was found in brick-earths, and everywhere in rocks containing the least trace of demonstrable uranium. In 1906, R. J. Strutt, to whom geology owes so much, not only here but in other lines of advance, was able to announce, from a systematic examination of rocks and minerals from various parts of the world, that the average quantity of radium per gram, was many times in excess of what Rutherford estimated as adequate to account for terrestrial heat-loss. The only inference possible was that the surface radium was not an indication of what was distributed throughout the mass of the earth, and, as you all know, Strutt suggested a world deriving its internal temperature from a radium jacket some 45 miles in thickness, the interior being free from radium.

Did time permit, I would indeed like to dwell for a little while on the practical aspect of measurements as yet so little used or understood; for the difficulties to be overcome are considerable, and the precautions to be taken many. The quantities dealt with are astonishingly minute, and to extract with completeness a total of a few billionths of a cubie millimetre of the radio-active gas—the emanation—from perhaps half a litre or more of a solution rich in dissolved substances can not be regarded as an operation exempt from possibility of error; and errors of deficiency are accordingly frequently met with.

Special difficulties, too, arise when dealing with certain classes of rocks. For in some rocks the radium is not uniformly diffused, but is concentrated in radio-active substances. We are in these cases assailed with all the troubles which beset the assayer of gold who is at a loss to determine the average yield of a rock wherein the ore is sporadically distributed. In the ease of radium determinations, this difficulty may be so much the more intensified as the isolated quantities involved are the more minute, and yet the more potent to affect the result of any one experiment. There is here a source of discrepancy in successive experiments upon those rocks in which, from metamorphie or other actions, a segregation of the uranium has taken place. With such rocks the divergences between successive results are often considerable, and only by multiplying the number of experiments can we hope to obtain fair indications of the average radio-activity. It is noteworthy that these variations do not, so far as my observations extend, present themselves when we deal with a recent marine sediment or with certain unaltered deposits wherein there has been no readjustment of the original fine state of subdivision, and even distribution, which attended the precipitation of the uranium in the process of sedimentation.
Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. L. BENEDICT is here.

LAWRENCE READ is at London.

E. P. MATHEWSON is at Salt Lake.

Cyril ROBINSON has gone to Europe.

S. P. SHAW is at Tombstone, Arizona.

THOS. H. LEGGETT has returned to New York.

GEORGE W. WILKINS has gone to British Guiana.

A. CHESTER BEATTY is at Pasadena for Christmas.

C. M. B. is visiting the mines at Taracol, in Korea.

SAMUEL LORD is in the Gowganda Lake district of Ontario.

ARTHUR THOMSON has returned to St. Louis from New York.

EUGENE BRAEN has returned to San Francisco from New York.

P. R. BEARDLE has returned from British Guiana to New York.

A. E. CARLTON, of Cripple Creek, is expected at Sylvanie, New Mexico.

DOWNS WATERSMAN is examining a mine in Calaveras county, California.

J. GORDON HARRIS is consulting engineer for the La Republica Mining Co., in Chihuahua.

G. H. RUSSELL and H. P. GORDON are doing some special mill-work at Murphy, California.

E. B. DUNHAM has been appointed associate professor of mining in the University of California.

D. L. H. FORNES is superintendent of construction for the Esperanza Mining Co., at El Oro, Mexico.

A. F. WURNSCH, of Denver, is consulting engineer for the Holcomb mine, at Sylvanie, New Mexico.

W. H. BURCE, of Denver, is on his way to Buenos Ayres, Argentina, to be gone for about five months.

MARRIAGE D. DRAPER is now manager for the Fifty Consolidated Gold Mines, at Blackhawk, Colorado.

J. B. TYSKEL has returned to Toronto after examining mines in the Sturgeon Lake district of Ontario.

P. R. WHITMAN is with the Virginia & Mexico Mine & Smelter Corporation, Hostotiquajo, Jalisco, Mexico.

HERBERT STUCKLAND has been appointed superintendent of the Black Rock mine, in Mariposa county, Arizona.

C. GUSTAV CASTILLO, general manager of the Syndicado Minero del Condoto, Choco, Colombia, is in San Francisco.

FRANCIS W. SEWELL, assayer, recently with the Great Boulder Proprietary mine, at Kalgoorie, has gone to Mexico City.

H. C. CUYLER, consulting engineer for the Nixon & Wingfield interests, has returned to Goldfield after a three weeks trip examining properties in Sonora, Mexico.

SCOTT TURNER has been appointed assistant to W. P. FERRIER, geologist to the United States Smelting, Refining & Mining Co., with headquarters at Redding, California.

THE PACIFIC COAST division of the Mining and Metallurgical Society of America held its second meeting at the Hotel St. Francis, in San Francisco, on December 19. Those present were M. L. REGA, C. W. MERRILL, S. B. CHRISTY, H. W. TURNER, F. W. BRADLEY, C. C. DERBY, CLIFFORD G. DENNIS, WHITMAN SYMMES, ALBERT BURCH, HOWARD D. SMITH, W. H. SHOCKLEY, CHARLES BUTTERS, T. A. RICKARD: also two guests, LATHER WAEGNER and WILLIAM ERH. S. B. CHRISTY was elected Chairman. Communications from Theo. B. COMSTOCK and F. S. H. MERRILL were read. The discussion of the best methods to protect investors was continued from the previous meeting. The next meeting will be held at 6:45 p. m. on January 30, at the same place.

**Geological Reconnaissance of a Part of Western Arizona.**

**Notes on a Collection of Fossil Mammals from Virgin Valley, Nevada.** By James W. Gidley. Bulletin of the Department of Geology of the University of California.

**Catalogues Received.**

The American Wellington Works, Aurora, Illinois, is distributing its Bulletin No. 105, which is a 200-page catalogue of well-drilling and prospecting machinery and accessories.

It is an unusually complete and well illustrated book.

The BAUCH & LEHR Optical Co., Rochester, New York, announces its 'Hand Book for Engineers' for 1909. This book, of vest pocket size, contains the Solar Ephemeris for 1909, and also directions for using the Sceau ultra solar attachment, now so universally employed. There are directions, with diagrams, for using and adjusting the engineers' level, the dummy level, and the transit, as well as other useful information. It will be sent free of charge upon request.

**L. Vogelstien & Co., New York, give the following figures.**

German consumption of foreign copper for the months January to October, 1908:

| Copper imports          | 125,347 pounds |
| Copper exports          | 7,342 pounds  |

Consumption of copper 128,905 as compared with consumption during the same period in 1907 of 96,395 tons. Of this quantity 124,405 tons were imported from the United States.
MINING

The copper mines in the Ketchikan district suffered a considerable setback early in the year because of the decrease in the market value of that metal, and except at the Jumbo mine operations were suspended during the winter. The Mount Andrew and Rush & Brown mines were idle throughout the year, as was the Mamie and Stevenon mines activities were renewed in August, and a relatively large amount of ore was mined, which was treated at the Hadley smelter. Explorations at these mines are to be advanced during the winter months, though the smelter suspended operations in November and no ore will be shipped. The largest production and most extensive developments during the year were made at the Jumbo mine, near Sulphur. The operations on this property were confined to the sulphide deposits at the head of Jumbo Basin, and only small developments took place on the copper-bearing magnetite deposits on the north side of that basin. The Niblick mine was operated from April 15 to October 30, during which period the shaft was sunk to a depth of 360 ft., and developments were extended on the 360-ft. level, where two orebodies were opened. Raizes were made in these orebodies to connect with the 325-ft. level, and most of the ore thus developed was mined. At the It mine, on Kasaan peninsula, mining operations were begun by the It Mining Co. early in the spring, and a body of high-grade copper ore was developed. A tramway one mile long was built to tide-water, a wharf was erected, and ore shipments were begun in the first part of October. The copper production of southeastern Alaska for 1907 will be considerably less than that for 1906, but the average content of copper per ton of ore mined will be somewhat greater.

ARIZONA

COCHISE COUNTY.

The Nashville company that owns the Gunsight mine, at Juniper falls, four miles from Bisbee, is preparing to install a mining plant at once and proceed with development. It is said that $50,000 is to be spent.—Reporta indicates that a large body of 15% copper ore has been found about 500 ft. south of the shaft on the 600-ft. level of the Shattuck.

GILA COUNTY.

The Inspiration property, eight miles west of Globe, is under option to New York capitalists, and it is said a large company will be organized to work it on a large scale. The Inspiration has about 15,000 ft. of underground workings and 1,560,000 tons of ore partly blocked out. It is said that W. H. Thompson, of Boston, and George E. Gann, of Salt Lake, are interested in the new company.

GRAHAM COUNTY.

The San Juan mines, at Safford, have started again and a force of men is now engaged overhauling machinery and pumping preparatory to sinking a new shaft. The company has built a new road from the foothills to the San Juan mine, a distance of several miles. The old road was completely destroyed last summer by a cloudburst. The pipeline from San Juan to Walnut Springs, from which the company gets the water supply for the camp, was also destroyed for about a mile near the spring by the big flood last summer, but has been repaired, new pipe put in place, and the well cleaned out. At Walnut Springs the company has a pumping plant, and the water is being pumped to the reservoir and water tank at San Juan.

MARICOPA COUNTY.

Herbert Strickland has been appointed superintendent of the Black Rock Limited mines in the Black Rock district. A mill was built on the property about a year ago, but proved inefficient in extracting the gold from the ore. The employment of a competent man to manage the plant is a step in the right direction and will probably result in solving some of the Black Rock’s problems. Mr. Strickland is a graduate of the Royal School of Mines.

MOHAVE COUNTY.

The Little Wonder Mining Co., operating the old Wildcat vein, in the Chemehuevis mountains, have a shaft down 95 ft. and have a vein of ore running four feet wide. This ore is said to carry 14% copper, 10% lead, $8 gold, and 20 oz. silver per ton. The company is to thoroughly exploit the vein and expect to prove up a good property. A whin will be placed at once at the mine shaft and excavation will be started.—Thomas Hogan is getting things in shape to begin work on his mining claims in the Thumb Butte section of Union Pass. Interested with Mr. Hogan in these properties are J. C. Potts and L. Kimmerly. The mines are known as the Golden Glance group, and have been explored to a considerable depth and have a splendid showing of gold ore. Mr. S. E. Barron and partners have completed a location work and will soon begin work sinking the shaft to a depth of 100 ft. They will have good ore in sight in this property and believes that he will shortly be milling ore from it.

YAVAPAI COUNTY.

Thomas E. Campbell, of Jerome, is directing operations at the Jerome Verde—formerly the Verde Queen—in addition to his duties as general manager of the Hayes Copper Company.

YUMA COUNTY.

The superintendent of the Big Stick Mining Co., with a force of men is at work dismantling the Sultan mine in the Santa Maria district. The mill will be installed at the Big Stick G. & B. Co. property and will be rushed as fast as possible.—The Ironwood & Arizona property, formerly known as the Griffin-Linn group, ten miles northwest of Salome, is about to change hands, and notices have been sent the stockholders to meet at Harqua Hual to consider the proposition of the Butte & Arizona Copper Mining Co., which offers $150,000 in stock for the L. & A. and will assume the indebtedness of $75,000 yet due to Griffin Bros. and Capy, Lind. The Butte & Arizona will be a company originally organized by E. A. Haggard to work the claims lying east of the well known Blue Bell mine, near Mayer, Yavapai county, before the closing of the Humboldt smelter.

CALIFORNIA

INYO COUNTY.

(Special Correspondence.)—The Buckeye M. Co. has awarded a contract for the erection of a 50-hp mill on its property at Fish Springs. The Company has opened up good reserves of low-grade free-milling ore and is employing a large force of men. At the 150-ft. level of the shaft a 56-ft. vein of 6 oz ore has been cut. Approximately $50,000 has been expended in developments. Manfield, Ohio, people, are interested. A. A. Casler is superintendent. The new adit at the north Inyo con. mine is in 1300 ft. A 20-ft. vein of low-grade ore was recently cut. M. T. Stovall is manager. A small vein carrying gold and silver has been struck in the Nichols mine at a depth of 12 ft. It is proposed to install a mill and cyanide plant. The mine lies near the Indian Queen. A small quantity of high-grade ore has been found in the surface workings of the Red Rose mine. A lower adit is being driven to cut the vein and is in about 250 ft. The Four Metals Co. has practically completed its electric light and power plant at Lone Pine. Ore from the old dumps at the Cerro Gordo is being sent to the Keeler smelter. Two shafts are being sunk at the Filer, the deepest being down about 65 ft. The vein is found in the Indian Queen. A small quantity of high-grade ore has been found in the surface workings of the Red Rose mine. A lower adit is being driven to cut the vein and is in about 250 ft. Two shafts are being sunk at the Filer, the deepest being down about 65 ft. The vein is found in the Indian Queen. A small quantity of high-grade ore has been found in the surface workings of the Red Rose mine. A lower adit is being driven to cut the vein and is in about 250 ft.

tion a number of miners formerly operating under lease have resumed work. Power is to be secured from the Terrible plant.
Georgetown, December 19.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The greatest activity has reigned throughout the Coeur d’Alene during the past week. In Murray a mass-meeting of citizens has been held for the purpose of preparing a suitable celebration on the arrival of the first train over the Idaho Northern railroad. The people of that town believe that this notable event will take place some days before Christmas, which has been substantiated by a statement issued by the president of the railroad company.—In view of the near completion of the Idaho Northern railroad, active steps have been taken toward the organization of a company to erect a smelter in the Little North Fork country. Already a number of Wardner men interested in mining throughout the district, have taken the matter up, and it is understood that the organization is also backed by a number of Portland capitalists. Those interested at the present time are T. R. Mason, P. F. Matchette, and George Harris, of Wardner. The new plant will have a capacity of 100 tons per day, and it is believed that this will be increased as soon as business warrants. The smelter will be entirely different from those already in use in other parts of the country and will operate the patent of Mr. M. A. North, who is in the district at present. The principal feature of the smelter is the fact that coal is used as fuel and that the cost of erection of the plant is only about one-quarter of the cost of the furnaces in use at present.—Stanly A. Easton, of the Bunker Hill & Sullivan mine and of the Pittsburg Lead Mining Co., has announced that work on the latter property, which has been closed down for some time past, will be resumed on the 1st of this month. In an interview the management asked the stockholders to make a return of 30,000 shares of treasury stock, made on behalf of Eastern investors through a Spokan firm of brokers, has been refused by the directors of the company. The main adit has been driven about 2100 ft. and it is expected that the vein will be struck at the 3,000 level. The owners are the beginning the management action for the protection of the stockholders and have made a return offer of 60,000 shares of treasury stock at 50c. per share.

Negotiations on the latter deal are pending.—W. A. McCune, of Salt Lake City, and Walter Mackay, of Portland, have purchased the Reno group of claims near the Great Western property in the Burde district. Under the new owners a strong force of men will be set to work by February and 50,000 ft. of adit will be driven within the year. The property was owned by Tom Ryan and Charles Eckols and has been extensively developed.—A deal has been closed by which the Castle Rock Mining Co. will ship a number of cars of ore to the Panhandle smelter at Sandpoint. The ore is valuable as a flux and a smelting company has agreed to pay the mining company at the rate of $4 per ton, freight and other charges, including freight and duty. The ore weighs about 25% from carbonate, 2 to 5% copper, $1.25 gold, and from 1 to 3% lead.—The Spring Gulch Mining Co. has paid $22,500 on its bond and arrangements are being made to take the balance of $12,000 in the near future. The company has made one shipment of ore on which they received returns of $135 per ton, but this is regarded as disheartening, as at least $950 was expected, hence shipments have been discontinued. As soon as the force of men is engaged at the mine under the management of Charles C. Pooley, of Mullan.—The vein of the Hypotheek mine in the Kingston district has been cross-cut, showing it to be 30 ft. wide. It is now the intention of the management to sink the shaft another 250 ft. and to cross-cut every 75 ft. The new hoist recently ordered has been delivered at the property and work on its installation has been started. About 150 ft. The drilling is being done from the face of the present adit, which has been driven about 1500 ft., and it is believed that in order to strike the vein, which was opened in the upper workings, 500 ft. more work will have to be done. It is the intention of the company to first test the ground by means of drill-holes and it is expected that the first of these will be completed about Christmas. Wallace, December 19.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—A number of important strikes have been made recently in the JoPlin district. A shallow lead strike was made in the Kansas City bottoms by O. Manwali, when a 1700-ft. chunk of ore was taken out at a depth of only 14 ft. The extent of the body has not yet been determined. The chuck had to be broken in pieces before hoisting. In the same vicinity a number of companies are working leases. The Three Johns Co. has struck ore at 40 ft. and opened a 12-ft. face of both galena and zinc-blende. A short distance away Carpenter & Morris are operating a lease at 45 ft. and have both galena and zinc-blende. This latter firm has been making a regular turn-in for several weeks. Other companies operating on the Edwards land are Amos Freeman & Co., the Lucky Jack, and Saum & Co.—A rich drill strike has been made on the Penrose land, at Carterville. The drill entered ore at 230 ft. and continued in ore till 240 ft. Two holes have been sunk. Prospecting is being done south of the Old Victor mine, which was once one of the best producers in the Carterville camp, and some showings of galena and zinc-blende have been found at 35 ft. by T. R. McDonald & Co., at Spring City. The shaft is now down that depth, though the drill-holes did not show ore above 60 ft. A lower run was disclose at 116 ft., but this will not be developed until later. For the present the ore will be treated on hand-jigs.—A company of prospectors has made a strike on the Granby land at Orogo near the old Dov Drop mill. The prospects and a 900-ft. adit. The property is extensive but work was not expected to be launched until the present season: The driving has not proceeded far enough to learn the extent of the deposit.—A number of old producers are being re-opened, among which is the Kohinoor that has been idle for years. A company recently began prospect work with the result that a shaft has been sunk and ore entered at 150 ft. The ore runs 8 to 10% zinc-blende. At a lower level a second deposit was found and in both instances the face was 20 ft. thick. The old mill, which was in a bad state of repair, has been overhauled. In the meantime a very rich dump-pile has been accumulating.—The Nor- tonia mill, west of JoPlin, has resumed operations after a long shut-down. More machinery has recently been added. The mill is furnished with ore from two shafts which are down 170 ft. The company is working upon the same run of ore as the Lucky Jim, which has been only recently started up. These two properties are the connecting link between the rich Continental tracts and the Smelter Hill group of mines.—The Little Jew mine, northwest of the Driving Park, has been taken over by Kansas City parties and will be re-opened at once. This property was shut down on account of low prices. The ore is found at 150 ft. and a mill of 100 tons capacity is on the lease.—A central pump has been put in by the Sunflower mine district, and the mine will be thoroughly drained and developed. The shaft will be deepened to catch the lower runs of ore. Operations stopped at this mine on account of the inability to handle the water.—The old Pleasant Valley mines south of Carthage have again entered the producing list. Just previous to last year’s panic a great deal of prospecting was done and a large deposit of ore was opened on the old workings. The force of men engaged at the mine under the management of Charles C. Pooley, of Mullan.—The vein of the Hypotheek mine in the Kingston district has been cross-cut, showing it to be 30 ft. wide. It is now the intention of the management to sink the shaft another 250 ft. and to cross-cut every 75 ft. The new hoist recently ordered has been delivered at the property and work on its installation has been started. About 150 ft. The drilling is being done from the face of the present adit, which has been driven about 1500 ft., and it is believed that in order to strike the vein, which was opened in the upper workings, 500 ft. more work will have to be done. It is the intention of the company to first test the ground by means of drill-holes and it is expected that the first of these will be completed about Christmas. Wallace, December 19.
lent orebodies opened up. The deposit occurs in flint and calcite and is the same in character as the Bullfrog and the Blackberry. A 200-ton concentrating plant is to be erected on the Trope land south of Webb City. It is to be built by the Ave Maria Co. on a 20-acre lease and will be jointly the lease where the terrible explosion of a few months ago occurred. A 300-ton mill is to be built by the Pinnacle Mining Co. at Oronozo on the old Hill Top lease. Work has already begun. The shaft is already in ore, but development has not been completed. The lease adjoins the famous Oronozo Circle group of mines, which are splendid producers. —The Quick Seven Mining Co. at Neck City is building a 200-ton mill on a lease on Spring river. A considerable quantity of ore was taken out during the sinking of a shaft, some nugget zinc being thrown into the bins, and the rest treated on hand-jigs. Drifts have been driven under the river, where some good ore has been found. —The Oronozo Circle Co. at Oronozo, has overhauled the No. 2 plant and connected it with shaft No. 5. The sludge from the mill will be sent to No. 5 plant, where special devices have been installed for the extensive handling of ore. As ore is coming from the old mill, the new mill will be connected to the old from the Black Fork. A new telephone system has also been installed. —Jessie & Shultz have started a sludge mill on the old Quaker land at Chitwood. The sludge from the abandoned mine will be run through the mill, which has a capacity of five or six tons per week. The sludge from the pond will be treated, as a large amount of the fine ore has settled in the old mill. Another plant is being erected by the Black Fork Mining Co. The ore is being cleaned on hand-jigs and is taken from the 150-ft. level. It runs as high as 15 to 20%.—Pulsating jigs will be installed in the Lincoln property at Duenweg. They are an innovation in that district and it is thought that the ore can be recovered more economically. The Lincoln is operating on sheet gravel, which runs from the blende to the blende. The vein varies from 12 to 22 ft. in thickness. The management will erect a 200-ton mill in the immediate future. —Seven carloads of silicate have been produced from the Hall land in the Duenweg district in the past four weeks. This has proved to be one of the best silicate producers of the district. A new shaft has recently reached the 100-ft. level. The entire crowd of mills. A company to be erected soon. When the new drifts reach the old ones a 15-ft. stope can be worked. Joplin, December 19.

NEWTON COUNTY.

(Special Correspondence.)—South of Joplin on Shoal creek the Ohring-Junge estate is to be worked. If ore in paying quantities is found a mill will be built. Five drift-holes, all showing ore, have been sunk. The failure in the early-day mining was due to the inability to handle the water. —The new company known as the Western has secured a 40-acre tract of land belonging to the Granby Mining Co. and will develop it thoroughly. About 1000 ft. of drilling will be done at once. The drills have been started and excellent signs of ore have been found. —The Homestake-Mascot Mining Co. is building a 150-ton mill which will be used for a sludge plant, and will handle the old tailing pile as well as those made now. The old pile is one of the richest remaining in the district, as it was made in the early days when facilities for saving the fine were not as good as at present. The old sludge pond will also furnish a large amount of ore. —Near Fairview a prospecting company has made a shallow strike of silicate which is expected to reach for the shaft depth. The ore was found at only 5 ft., where both silicate and zeolite were cut. The extent of the discovery is not known, as the tract has heretofore been virgin ground. Granby, December 19.

NEVADA.

ESMERALDA COUNTY.

The Tonopah & Tidewater railroad has announced a material reduction on freight rates for southern Nevada ores. All districts will be benefited by the new rates, but Gold

field will profit particularly. The new and old charges are as follows:

<table>

The Henry Clay M. Co., operating on the Crackerjack property, is developing some veins which assay as high as $29 per ton. The company expects shortly to erect a 10-stamp mill. —The St. Ives lease continues to send occasional shipments to the mill, the ore coming from the small sheet uncovered on the 50-ft. level of the old workings several months ago. A. A. Cod is the manager. —J. C. McConnell, president of the Broken Hills M. Co., reports that the 50-ton mill, which the company is to erect at Helena, will be in operation by March 1. This company has installed a hoist over the big shaft at the top of the hill, and a hoist will be put up over the new vertical shaft, which is 200 ft. farther down the hill, and has reached a depth of 80 ft. The company continues to make regular shipments to the mill, but will soon be curtailed, and the greater part of the ore held to be treated later on the ground. —The Great Western mine at Hornsilver struck ore at its 300-ft. level, assaying about $34 per ton in gold and 6 oz. silver. E. A. McNaughton is superintendent. —The Hazed Goldfield M. Co. made its first shipment of ore from the lease on the Laguna last week. The shaft is down 740 ft. and will be sunk 100 ft. farther if the vein continues rich.

LINCOLN COUNTY.

The Lincoln-Nevada M. & M. Co., owning property near Pioche, has been re-organized, and Charles B. Bond, of Col- umbus, Ohio, elected president, and W. M. Jackson, of Mar- ien, Ohio, chosen as fiscal agent. The capital was also in- creased from $1,000,000 to $1,500,000. The new management will proceed at once with the development of its property. —The Storm Pete Pioche Mining Co., of which Hans Olson is president, has let a contract to Fields & Burgess for a 50-stamp mill on the Gypsy group of claims in the Stampede district. —The new machinery of the New York mill, which has been overhauled and is now being put in shape. It includes a 25-hp. gasoline hoist, a 35-kg. generator, a six-drill compressor, and minor pumps and tools. The existing 240-ft. shaft will be deepened to 500 ft. before any lateral work is done. W. W. Hart is general manager. —The Old Mizuno Co. is to start work on its property at Camp Thur- man. M. D. Jackson will have charge of the work, and also manage the operations of the Missouri-Nevada, at Cresent. John Wheatley, acting for the Nevada-Kingston Develop- ment Co., has started work on the Gaviann. This company, which is the successor of the Searchlight Treasurer Gold Mining Co., controls the mineral rights of the original town site. According to advices from New York, continuous operations may be expected.

EVE COUNTY.

The Sierra Oro Mining Co. will be organized to work the Jim Dandy claim, immediately northwest of the Bullfrog Pioneer property, at Rhyolite, on which the strike was recently made. H. N. Nichols is the moving spirit, and J. B. Bryan will be superintendent. —The Tonopah Mining Co. has declared a dividend of 25c, per share, payable January 21, 1909. The distribution amounts to $250,000, and makes a total of $750,000 returned to stockholders this year. —The total output of the Tonopah mines for the week ending December 19 was 5523 tons, of an estimated value of $135,300.
WARWICK COUNTY.

J. B. Monardi has been appointed receiver of the Selby Consolidated mine, at Jumbo, near Rezo. The liabilities of the company are $18,000, and the assets only $5000. It is claimed that the stockholders lost $300,000, and rumors of fraud and ‘railing’ are freely circulated. A $20,000 mill has been built and has produced only $4000. Among those interested are W. R. Gilbert, J. W. Campbell, A. Y. Werner, and Fred Stadtmueller.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence.)—The lower adit on the Knob Hill mine, near Danville, is now in about 1200 ft. and almost directly under the shaft, to which a raise will be made. That done the company will begin stoping ore and get ready to ship. Fifteen men are now employed.—The Belcher Mining Co. has 14 men employed. The stockholders have agreed to place one-fifth of their holdings in the treasury, which some of the larger stockholders have agreed to sell, for the purpose of pushing development work on the mine.—The Colville M. & S. Co. is preparing to ship a carload of ore to each the Tacona, Washington, Sandpoint, Idaho, and Carnegie, Pennsylvania, smelters. No ore will be shipped at less value than $100 per ton. G. Weaver Loper, the president of the Company, states that the Miners’ Smelting Furnace Co. has entered into a contract with the Colville M. & S. Co. for the purpose of furnishing the latter corporation two Medberry rotary smelting furnaces. The vendors give a guarantee that, with the character and quantity of fluxes to be used, the Colville Co. is to secure the same results as could be obtained if the ore were shipped to the custom smelters. The guarantee further provides that the returns from the ore smelted shall be equal to those obtainable from the American S. & R. Co. The object of shipping carload lots of ore to distant smelters is to ascertain what results can be had from them and to see that the Miners’ Smelting Furnace Co. will live up to its contract.

Republic, December 18.

OKANOGAN COUNTY.

(Special Correspondence.)—The Oroville Consolidated Mining Co., operating the Blue Bell group, near Oroville, has discovered rich copper ore on a contact vein, between dolomites and slate, which has been stripped over 100 ft. in length. The ore contains considerable chalcopyrite and some gray copper. There are other veins on the group, but this is the most valuable discovery yet made on the property. The Conconnally Copper Co. is getting out ore for immediate shipment. The Oregon & Pacific, British Columbia, and will increase its working force next month.—The Ruby Mining Co. has decided on building a concentrating mill on its property on the Similkameen river and will ship no more raw ore.—The Golden Charlot mine, on Kruger Mtn., is being watered, to take out ore for shipment.—The installation of electric power at the ‘Hine mine is nearly complete and will soon be available for the Kimberley and other neighboring miners in Golden Camp.—The Forty-ninth Parallel Mining Co. has begun work on a group of claims that were formerly productive of rich copper ore, and expects to begin shipping early next spring, or as soon as railway transportation becomes available. The property is situated between the Kelsey group and international boundary line, on Kruger mountain.

Nighthawk, December 19.

STEVENS COUNTY.

(Special Correspondence.)—The First Thought mine is giving employment to 39 men and sending to the smelter 38 tons of ore per day. The working force will be increased as soon as the compressor is installed and power drills can be used. A body of ore richer than any ever before found in the mine was uncovered about a week ago.—It is expected the present contract on the North Star mine will be finished by the end of the month. Some fine ore has been discovered in the new workings. A new adit will be started the first of next year, to be driven 600 ft.—The First Thought Extension Mining Co. is employing six miners sinking a shaft which is down 84 ft., all in ore of good shipping quality and said to assay from $40 to $50 per ton in gold. This company is erecting an assay office, stables, and shaft-houses and will soon begin shipping ore. The vein is 35 ft. away from the cross cut, which will be driven as soon as the shaft reaches the 100-ft. level, when the actual width at that point will be determined.—A cross-cut was being driven from the bottom of the shaft, on the 100-ft. level of the Copper Butte mine, on Toulan Mtn., but the work was suspended on account of inconvenience in hoisting. A hoisting plant will be installed immediately, and the shaft will be sunk to the 200-ft. level. Some fine-looking copper-gold ore has been found on the 100-ft. level, upon which a drift will be driven.—Work has been resumed by the British Columbia Copper Co. on the Napoleon mine, above Kettle river, with a force of about 40 men.—In Chewelah district a body of high-grade copper ore, 25 ft. wide, was recently cut while stoping in the United Copper mine, that being the greatest width of the vein, which narrows to six feet in places. The company is employing 35 men, and has one team and two horses on the railway, in transit to the smelter. Several more teams will be added, in order to ship all the ore possible while the roads are good. No dead work is being done in the mine at present. The adit on the 400-ft. level is in 1315 ft.—The Blue Bell and Blue Bell No. 2 claims, in the copper belt, three miles from Chewelah, have been sold to A. H. Anderson, of Coeur d’Alene, Idaho, who will place machinery on the ground and begin work on the property.—The Tungsten King Mining Co., Deer Park district, has refused to bond its property and will continue developing it. In the shaft there is now reported to be nearly 50 in. of solid wolframite. The upper vein is now 34 in. wide, and the one that was uncovered two weeks ago is about 14 in. wide. In the intervening porphyry a new vein is coming in.—The McKinley Mining Co. has been incorporated with 4,000,000 shares of capital stock at $1 each, of which 400,000 shares have been placed in the treasury. Orient, Washington, is the principal place of business. The incorporators are J. H. Pelkey, James D. Grimes, George Weaver, all of Orient, and C. F. Wikstrom, of Spokane, Washington. Mr. Wikstrom, the principal shareholder, will be the president and Mr. Pelkey the superintendent of the company. The company owns nine claims in a group, in Pierro Lake district, and the boundary of the property extends from the No. 1 claim is traversed by a quartz vein 10 to 12 ft. wide, which is traceable a mile and a quarter. It has an open-cut on it which exposes ore that assay $14 in gold and copper. In the open-cut the hanging wall and foot-wall are 34 ft. apart. On the No. 2 and 3 claims open-cuts have been driven across an 8-ft. vein, in one of which is 6 ft. of good ore, assaying $10 in copper, gold, and silver. Some of the ore shows chalcopyrite, cuprite, and molybdenite and is rich. The No. 4 claim has an open-cut 8½ ft. deep at the breast and exposes gray quartz. The vein is nearly 8 ft. wide, and a shaft is being sunk on it. On the No. 6 and 7 claims but little work has been done. On the No. 8 is a shaft 82 ft. deep. At 22 ft. below the collar a vein appears dipping at an angle of about 45°. Another vein, 26 in. wide, was cut through at the bottom of the shaft, having a vein 2 in. wide, which was above the 400-ft. level. On the intervening veins, the country rock is well mineralized, and average samples assay about $10 per ton in gold, silver, and copper. On the dump of the No. 8 claim are about 40 tons of ore ready to ship. The company will soon equip the shaft with light hoisting machinery, which may be removed from one place to another and be used in prospecting the several veins. The ore will be shipped by surface. The company will begin shipping late next spring. The company will transact business through the Bank of Colville, at Colville, Stevens county.

Orient, December 17.
Special Correspondence.

MEXICO.

Zinc Mining in Chihuahua.—A Misleading Report.—Absurd Statements.—Some Facts.

Mining men about Chihuahua are more than annoyed by the silliness of the American Consul at that point and at the case with which he lent himself to the interests that are fighting against the entry of Mexican zinc ores into the United States free of duty. It seems that there recently appeared in Chihuahua a representative of the Joplin zinc men to gather information that might benefit his clients in their fight before the American Congress. This honorable gentleman represented himself as wanting to buy a zinc property and so sailing under these false colors was presented to a number of operators who had properties for sale and who naturally put the matter to the supposed buyer in the best possible light, as to large bodies of ore, cheap labor and extraction, and simple separation in the case of complex sulphides. With such information as a basis, the said honorable gentleman gets up a report, presents himself to the Consul and apparently having credentials from the United States Government in which the various Consuls are probably asked to lend aid, persuades the Consul to put his name to the paper and send it in to Washington as a Consular Report, and so have it appear as official. No one knowing the Consul at Chihuahua can help but smile at the thought of his sending in such a report, for he probably knows as much as a child regarding the zinc mining in Chihuahua or elsewhere. The report names some of the principal points in Chihuahua from which zinc is shipped, and then goes on to state that the zinc occurs with lead or lead-silver ores and so partakes of the development of the latter, though some may be called zinc mines, but "in every case, however, silver-lead ores are those sought for and mined." It is further reported that as a conservative estimate there are 1,900,000 tons of zinc ore in reserve, distributed at Picheos, 50,000 tons; Santa Eulalia, 200,000; San Isidro, 100,000; Almoloya, 50,000; and Parral and Santa Barbara, 600,000; with probably more in depth, as with one exception (where the zinc is a by-product) none have yet reached any great depth. And there is one instance cited where the zinc is mined by a tunnel, where the ore is "simply broken down and run through chutes to the mine-car"—almost as good as the "Ladies' Home Journal" story of the little children in Denver going to the creeks with their buckets for gold nuggets as other children would go to the woods for berries. Of the complex sulphide ores it is stated that the zinc in them is no longer a detriment, but is now a profitable by-product because of the simple means of separation available.

This report will receive official endorsement by reason of its having been sent in as a United States Consular Report. A more flagrant misrepresentation of the facts, either due to ignorance or with the direct purpose to deceive, could not readily be conceived. What are the facts? There is scarcely a zinc property in Chihuahua that is not worked wholly for the zinc. The principal one at Picheos has some lead in the vein, but has not yet been able to get a clean enough lead product that would pay to ship, and if there are more than 2000 or 3000 tons of ore in sight no one in Chihuahua knows it except the owner of the property, than whom there are people more reliable. The single deep mine "where zinc is a by-product," is in truth owned by a lead-silver mining company (often spoken of as the greatest in Mexico), but the body of zinc ore is wholly apart from the lead deposits, and is separately developed and mined, and has only the advantage of being exploited under the same organization as the lead mine. The property at San Isidro is known as the largest zinc mine in Mexico, and may be considered as wholly zinc, for after treatment in an expensive mill by a costly dry separation, the lead product amounts to but two or three cars per month—scarcely worth considering. Almoloya may be disregarded; but what of the 1,900,000 tons of ore in reserve at Parral and Santa Barbara? Of what use is this stock, if there be such an amount? This ore belongs to the complex sulphides that by reason of "simple separation" processes are "not now a detriment," but in connection with which no mention is made of the immense and expensive mill of the Monteuma Lead Co., a monument of failure within sight of Santa Barbara station and representing an outlay of perhaps $1,000,000 or more: of the San Diego, the Alfa-rea, and the Grenadea mills, around the hill from the Monteuma, and still problematic after several years of operation; of the San Francisco del Oro and its heavy expenditures on various processes of separation, only to meet with failure and a complete shut down. The report does not tell that the Teocotes of the Guggenheim Exploration Co. is the only mill in really successful operation on these complex sulphides in the Parral-Santa Barbara district, and this success only after many failures, many shut-downs, expensive alterations; and only by large tonnage does it just barely keep operations on the credit side. Such are the reports being presented to the United States Congress. When the Consul sends in such reports, the State Department should certainly advise the "shoemaker to stick to his last."

PACHUCA, MEXICO.

Real del Monte.—Loreto and Guerrero Mills.—Details of Process.

The Real del Monte of Pachuca is milling 15,000 tons of ore per month, and shipping 450 tons of high-grade ore. The mill-tonnage is divided equally between the Loreto works, at Pachuca, and the Guerrero, situated below the town of Del Monte. The Loreto receives ore from the Camellia and Baron mines, the Guerrero handling the ore from the San Ignacio, Dificultad, Doleria, and other mines on the Del Monte side. The Loreto treats ore of an average value of $56 per ton, and that going to the Guerrero yields $50. The process at the two mills is identical. It consists in crushing in cyanide solution, concentrating, tube-mill grinding, and cyaniding in slime-tanks. At the Loreto the concentrate amounts to 245 tons per month, the gross value of which is $487 per ton; at the Guerrero the output is 218
tions per month, assaying 4.06%. The average of the ores received at the Loretto is 1 kg. 350 gm. silver and 5 gm. gold per ton, and 4% iron; the concentrate shows 36% iron, 10% zinc, and 0.5% copper. The copper, and a small percentage of manganese, are mostly taken out by concentration. The 40-ton mill at Loretto is 120 tons of material per hour, the second wash 40-mesh screen, a weak cyanide solution being used in the batteries; the 14 Chilean mills, of the old Pachuca type, running 14 rev. per min., crush 220 tons of crude ore per day. The pulp from the stamps and Chilean mills passes to 27 Johnson vanners, the tailing from the latter going to Dorr classifiers. The sand taken up by these classifiers is ground to 200 mesh in tube-mills, and is then drawn into agitating tanks with the slime that comes direct from the Dorr classifiers. The latter has been in use for five years. The tank is a Krueger mill, and one is made by the Denver Engineering Works. It is an all-slime process after the material leaves the vanners. 90% of the slime in the agitating tanks being 200 mesh. The agitating period is 36 hr., the first treatment being with a 0.15% solution, which is raised to 0.20 by the addition of fresh KY. The solution, after agitation, is decanted, and the tank filled with a second treatment-solution carrying 0.15%, and again agitated. There are 27 of these agitating tanks. Each charge is given three to five treatments, according to the character of the ore. The decanted solutions are all passed direct to the precipitation boxes, and the decanted slime is pumped to fluters filters, the total extraction of the gold and silver being 95 per cent.

The Guerrero mill is supplied with ore by a aerial tramway, 6000 ft. long, from the San Ignacio, Difficultad, and Dorce silver surface mines. The surface mill buildings of the scrap and Coburn mines. The mill-bin has a capacity of 2000 tons, with pockets by which the ore from different mines is kept separate prior to sampling, after which it is mixed. There are 40 stamps, each weighing 1050 lb., having a 8-in. drop, 106 per minute. The mortars are of the El Oro design, with narrow discharge and wide base, set on concrete foundations. The screens are of No. 19 wire, set to give 3% in. height of discharge. The batteries from the new and Coburn mills are Dorr, and one is made by the Denver Engineering Works. It is an all-slime process after the material leaves the vanners. 90% of the slime in the agitating tanks being 200 mesh. The agitating period is 36 hr., the first treatment being with a 0.15% solution, which is raised to 0.20 by the addition of fresh KY. The solution, after agitation, is decanted, and the tank filled with a second treatment-solution carrying 0.15%, and again agitated. There are 27 of these agitating tanks. Each charge is given three to five treatments, according to the character of the ore. The decanted solutions are all passed direct to the precipitation boxes, and the decanted slime is pumped to fluters filters, the total extraction of the gold and silver being 95 per cent.

The Butte Coalition Co. has begun the use of the new Tramway shaft and hoist for mining operation in the Minnie Healey and a portion of the Rarus mine. The Tramway vein will also be mined through the new shaft. The shaft is something more than 1600 ft. deep, and will be sunk deeper while mining progresses on levels 13, 14, and 15. Level 16 is being opened from the Tramway through Tramway ground and into the Minnie Healey. With the operation of the new hoist the output of the company, which is now from 1900 to 2200 tons of ore per day, will be increased gradually until a few months hence, at least 2500 tons will be hoisted daily. The new surface plant at the Tramway is one of the largest and best in the Butte district, and was designed to serve largely for all the operations in the Rarus-Minnie Healey group of mines, including the Tramway and Snoumoish mines, in which the Coalition owns controlling interests. The new engine, made by Allis-Chalmers, is a Cervlex type, with 32 by 72 in. cylinders, capable of hoisting the seven-ton skip from a depth of 3500 ft. It is equipped with drums 12 ft. diam., on which are wound 1½ in. steel ropes. The plant includes a large boiler house with equipment, carpenter shop, hoisting-engine building, miners' change-house suitably constructed, with hot and cold water and shower baths, capable of accommodating 1500 miners; machine shops, warehouse, and office building. The steel head-frame is 92 ft. high to the sheaves. In addition to the large hoisting engine, another engine of good size is in use for sinking and lowering supplies and handling the men, through the third compartment of the shaft. Excellent results have been obtained by the developments on the lower levels. They have practically made a new mine out of the Minnie Healey. Level 13 is 60 ft. below the lowest mine of the old workings on the 1100-ft. level. That 60 ft. of ground will be necessary to hold back the fire and gas from the upper levels. The vein is said to be more than 35 ft. wide, but more than a dozen other veins of varying sizes have been opened on level 13, the smallest being about 4 ft. wide and very high in grade. Similar conditions prevail on level 14. On the 1500-ft. level the largest vein opened is more than 50 ft. wide, and 55 ft. of it is rich. Another vein is 25 ft. wide and carries considerable copper glance. On level 16 in the Tramway vein is more than 30 ft. of good commercial ore.

New change-houses have been built at the High Ore, Berkeley, and Gagnon mines. New ore-bins have been built at the West Colusa, and a new boiler plant installed at the Berkeley. A new electric hoisting engine has been put in at the West Gray Rock. A new compressor has been installed at the Leonard, as well as new machine shops, carpenter shop, etc. The big hoisting engine at the Bell mine has been transferred to the Little Mina, the Bell being operated through the Diamond shaft. The new hoisting engine at the Pennsylvania mine, lately installed, is similar to that at the Tramway; it is of the same make and capacity. A new boiler plant has also been put in at the Pennsylvania, a new steel head-frame erected, and new skips installed.

During the present year the Gannan shaft has been deepened 200 ft., its present depth being 2200. The Diamond, which is down 2200 ft., is also being sunk deeper, as are the Leonard and Little Mina. The North Butte Co. sank the Speculator shaft 400 ft. farther, and sinking is in progress at the Rarus, the Tramway of the Coalition Co., and the Original, Pocer, and Elm Orulu of the Original Company.
JOHANNESBURG, TRANSVAAL.

In a recent communication, reference was made to the disappointing results obtained in actual working practice by the Gordon drill, which won with such remarkable ease in the trial last January. The urgent need of an efficient light drill, hammer or percussion, to displace native hammer-boys in stops of narrow width, and the admirable performance of the Gordon drill in prior trials, make this failure particularly deplorable, though the last effort to produce an economical hammer-machine has by no means been made. A lawsuit is now proceeding in connection with the Gordon Drill Co. (too complicated for brief report and will sub judice), in the course of which several interesting opinions have been given by miners, called to the witness-box to state their experience with the drill. The foremost trouble has been, it is stated unanimously, with the anvil-blocks, which have lasted a few minutes or a few hours, rarely over a day or two. If soft, these blocks ‘swell’. If hard, they break. Repairs have consequently been a prohibitively heavy charge (about £20 per machine per month) and have placed the drills out of use for an excessive proportion of the normal running time. The ratio of down-time for repair has also been a source of trouble, owing to the teeth being too fine. When the anvil-blocks break, damage may frequently he occasioned to other parts before the fracture is discovered and the drill can be stopped, the blows of the little hammer being so rapid. While the principle of the Gordon drill may yet be turned to good account by a strengthening of construction, the supporters of light percussion stope-drills have been appalled by the belief that the best lines of the experience of the last year has clearly demonstrated that the process of stope-drill manufacture on novel lines is one better befitting the energies of a well-financed company than of the ‘practical man’ and that an outlay of a few hundred pounds is of small avail for the accomplishment of final results.

All applications from America for entry in the forthcoming stope-drill contest should have been despatched, for the list closes on December 31. The many communications received from the States by the Committee inspire the hope that many new ideas will be brought to public notice by American manufacturers. Similar complaints to those heard a few years ago against the Witwatersrand Native Labour Association, expressed on the belief that the results obtained from open recruitment have recently been voiced by a group of Rhodesian operators against the Native Labour Bureau of that territory. Naturally the trouble has arisen in a period of shortage, when dissatisfaction is easily kindled. The Bureau was formed to establish co-operation in place of competition among employers of native labor, and any effort to break up the institution would surely be economically disastrous even though independent recruiting might be advantageous to a few at the moment. The present ‘opposition’ comprises a number of small operators in the Hartley district.

South African diamond companies are rarely talkative. Liberal permission is granted visitors to inspect the mines and plants, but questions of policy and results receive only brief mention upon the issue of annual reports or at general meetings. During the present period of acute depression in the diamond market, directors have been particularly reticent, preferring to risk unchecked chatter than official publicity, which might weaken their hands in the battle of commercial competition. On this account, the statement published by the Premier Diamond Co. as to the results obtained during the half-year ended October 31 has presented a surprising pluck with which a vigorous technical policy has been pursued in face of external difficulties. The salient features of the report are the cost reduction and the maintenance of output. During the last five years returns have been:

A load is 16 cubic feet.

The total cost per load has been reduced from £2, 4d. in 1907 to 19d. Values have not yet been announced.

It is indeed gratifying to observe from a report issued by the Eckstein concern, the Transvaal Consolidated Land & Exploration Co., that at least one profitable lode-tin mine has been established in the country as the result of the extensive and often financially disastrous prospecting done in recent years. Stream tin was found on their farm Greenfontein in the Waterberg district (north of Pretoria) in 1906, and subsequently a rich deposit was discovered in the immediate vicinity. A large sink has been erected and shortly 100 tons will be treated per month, as compared to the 1900 tons for which the plant was originally designed. Good profits have already been recorded, and during the five months ended August 31, 4267 tons were crushed, for a yield of 418 tons of concentrate, containing 70.6% metallic tin, and valued at £52,269. Of this amount £13,295 was accounted for by working expenses, leaving £38,974 as profit. These figures are the first that have been available in regard to a profit-making tin-mine in the Transvaal. The directors state that the fuller knowledge of the nature of this Greenfontein deposit lends to the belief that not only will the rich lenses prove to be more persistent than anticipated, but that there is a probability of large bodies of low-grade ore being discovered. The alluvium may also be worked profitably. The chief Greenfontein deposit comprises a lenticular mass of coarse graphic granite, partly pegmatized with casiterite, which replaces feldspar and sometimes even quartz.

Questions relating to the claims of various gold mines for pre-eminence or to goldfields for the distinction of foremost richness are ever of lively interest. As a rule, a diversity of conditions renders each case of primary importance and the circumstances sometimes give an uncertain result. Without, therefore, attempting contrasts, we may ascertain what the richer (central) section of the Rand is now doing. The central section may be taken to comprise 15 mines (out of 63) and to cover four miles along the strike. Taken in order from west to east, these producers recorded the following returns for September:

- Langaatge 45,500 £2,499 £24,290
- Langaatge Deep 40,338 52,345 18,125
- Crown Reef 24,500 39,106 20,690
- Crown Deep 38,865 67,883 29,011
- Robinson 44,700 111,281 84,489
- Robinson Central Deep 30,378 66,617 45,323
- Robinson Deep 54,977 94,189 51,929
- Ferreira 24,190 57,055 35,858
- Ferreira Deep 33,000 77,555 50,985
- Village Main 42,190 62,296 20,881
- Village Deep 29,190 39,134 17,045
- Salisbury 7,650 8,716 2,912
- Jubilee 5,236 7,034 2,332
- City & Suburban 25,800 27,805 8,095
- Meyer & Chariton 15,125 19,816 8,652

Total for four miles... 462,450 £786,678 £420,644
Total for Rand... 1,554,755 £2,491,831 £1,265,362

This small section is seen, therefore, to account for over two-fifths of the Rand’s entire profits. Its gold-producing capacity may be placed roughly at £2,400,000 per mile per annum, and its profits at nearly £1,300,000 per mile. The inclusion of the old Jubilee and Salisbury mines—small properties standing aloof from amalgamations—provides a striking reminder of the humble standards obtaining in the early days of Johannesburg’s development.
Concentrates.

Most of these are in reply to questions received by mail.

The largest Sequoia, or ‘big tree’, as it is sometimes called, is said to be 325 ft. high, with a maximum diameter of 35 feet.

The specific gravity of storage battery cells should never be adjusted until the cause of the change is found and remedied.

Arkose is the name applied to a variety of sandstone containing a large amount of feldspar grains. It usually shows mica and many other silicates, indicating that it originated from the erosion of granite rocks. A large number of sandstones are in reality arkose.

Hand-sampling of ore fed to a mill, and of the products at various stages in the milling process, is liable to gross error, even when conscientiously done. Automatic sampling should always be adopted. In designing a mill ample grade should be allowed for that purpose, a detail commonly neglected.

Machines with reciprocating motion should be driven by an adjustable-speed, compound-wound motor. The latter feature is specially useful, in that at the instant of reversal of the machine-tool, when the torque required of the motor increases above the normal, since it assists materially in holding the ingress of current within reasonable limits. A flywheel also assists in such a case.

Obstinate sulphation of storage battery cells may be remedied by removing the electrolyte and replacing with water. Allow it to stand for two or three hours. If the specific gravity is below 1.060, add electrolyte to bring it to about that figure, and if too high, add water. Charge the cell at the normal rate for eight hours after the density and voltage cease to rise.

The properties of copper wire, according to the Brown & Sharpe gauge, may be conveniently carried in the mind with the help of the following hints. A wire which is three sizes larger than another wire has half the resistance, twice the weight, and twice the area. A wire which is ten sizes larger than another wire has one-tenth the resistance, ten times the weight, and ten times the area. No. 10 wire is 0.10 in. diam.; it has an area of 10,000 circular mils; it has a resistance of 1 ohm per 1000 ft. at 20° C., and weighs 32 lb. per 1000 feet.

Copper ores of low metallic content are being developed extensively in many places. The great mines of the Utah Copper and Boston Consolidated Mines in Bingham canyon, Utah, produce ores that will not average above 1.7% copper, and the disseminated ores of Ely, Nevada, constituting the basis for the operations of the Nevada Consolidated, will average but little higher than 2%. It is well for prospectors to examine the surrounding crystalline rocks on seeing indications of copper. It may happen that the country is more valuable than the small, though more highly enriched, veins that traverse it.

Stadia measurements are now accepted by the U. S. Land Office for the determination of distances in the survey of claims for patent. Such a ruling has been in force in the neighborhood of three years. The stadia is designed to secure rapidity rather than accuracy; but on particularly rough country, using especial care in the field and extra refinements in the reduction of observations, it should exceed the tape-line in accuracy of results. The degree of precision is dependent upon the magnifying power of the telescope, the length of sight, and the ratio of the space on the rod to the corresponding space on the ground.

The Italian method of tunneling is essentially a treacherous-soil method. It consists in excavating the bottom half of the section by means of several successive drifts and building the invert and sidewalls: the space is then re-filled and the upper half of the tunnel-section is excavated and the remainder of the side-walls and the roof-arch are built; finally, the earth-filling in the lower half of the section is re-excavated and the tunnel completed. The method is an expensive one, but it has proved remarkably successful in treacherous soils. It was first used in driving the Cristina tunnel, on the Poggia & Benevento railroad, in Italy.

The United States Land Office does not, nor did it ever, prescribe that solar observations should be used in determining the true meridian for patent surveys of mining claims. The U. S. Surveyor General, at San Francisco, informs us that such is the case, and that, as a matter of fact, the majority of applications passing through his office are based upon surveys in which stellar observations have been used. The usual limit of accuracy attained in patent surveys, using the direct solar observations, is probably within three minutes. Of the three common methods, stellar, direct observation, and solar attachment rank in accuracy in the order in which they are named.

Jamesonite is the sulph-antimonide of lead (PbSbS₄), containing 50.8% lead and 20.5% antimony. On account of its occurrence in masses of hair-like crystals, it is also known as ‘feather ore.’ It is gray in color, with a steely lustre. Large deposits are rare; in fact, it never constitutes a commercially important ore, although it is often present in notable amount with galena, stibnite also being present. Antimonial lead ores are not in demand, and at the present time the antimony market is exceedingly dull. Under exceptionally favorable conditions a large deposit of jamesonite, free from arsenic, would enable its owner to control the American market for antimony.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Dredging on the Seward Peninsula.

The Editor:

Sir—I have read the article by T. A. Rickard entitled 'Dredging on the Seward Peninsula,' in your issue of November 28, in which a severe slaying of the affairs of the Nome Mining Co. Though I must confess the criticisms, in general, are fairly warranted, I wish to correct certain imputations concerning the management during the past season, as also certain statements that are by no means based on facts or research.

If the writer of this article had been conscientious or charitable enough, during his visit of perhaps 10 minutes on the dredge, to have inquired of the manager his connection with the enterprise, or given him a chance to explain certain questionable things, he would have secured some knowledge which might in a way mitigate the severity of certain caustic remarks.

My connection with the Nome Mining Co. covered a period from the middle of June to the early part of September of this year (the dredge sank on August 14) and nearly a month of this time was taken up in getting the dredge in shape to launch. When I started for Alaska it was with the understanding that the dredge and power-house were in shape to run, with the exception of a few days for making the necessary adjustments. I was also informed that the contractor would bring his own crew and make the usual 30-day test-run. In addition, it was understood that all accounts for labor, etc., were taken care of, so that my early connection with the project naturally seemed very auspicious. This information had its origin in the owner and former manager of the property, and you can appreciate my disappointment on arriving in Nome to find conditions altogether different. The dredge and power-house were not nearly completed, and some material, supposed to be on the ground, had not arrived. It was also ascertained that certain very necessary apparatus had not been ordered at all, making it obligatory to borrow material that, in some cases, was not suitable, and also resort to make-shift parts until proper stuff could be ordered.

In the meantime, I learned that the contractor, previous to his arrival this summer, had been paid in full for his dredge, and the men were looking to me for their transportation from the States, as well as for the labor account. The 30-day test was a myth, and after a short time I saw little of the contractor. My first impression naturally was to accept defeat, and retire from the field. Thinking, however, that the crew brought into the country by the contractor would be of the best material from California (some of these men came from Oroville), I planned to go ahead and take chances. Assuming the manager wholly inexperienced, as the writer of this article claims, was he not excused from going to Oroville or Marysville to secure a capable dredge-master, and under these conditions should he be so un sparing as to discharge these men and seek others, without evidence of their incapacity? There was a dredge-master in charge of the boat, and though he was a man we could depend on, he was not a mechanic, and as the electrician in charge of the power-house showed greater ability in this line, I naturally had him look after the general details concerning the dredge. I wish to emphatically state that no one connected with the work at Nome this summer had anything to do with the designing of the dredge or power-house, except in the manner of strengthening—by braces, and other means—many weak parts of the machine.

Regarding the dam: when everything was ready for launching I was informed by the contractor that there would be required 4½ ft. of water to float the dredge. A suitable dam was constructed, but owing to the very dry season, which prevailed during the early summer throughout Alaska, it was difficult to get even the supposed necessary amount of water. It is not surprising then that the original dam was somewhat low when it was ascertained later that the dredge had a draft forward of nearly 6 feet. This dredge was originally designed as an open-chain type, having 33 buckets and a like number of links. For some reason, the former manager inducted the contractor to put on a closed-bucket line. This digging portion of the machine weighed 105 tons. The dredge was unquestionably not suitable, but as the contractor had no money there was very little satisfaction in looking to him for compensation or redress. It was up to me to go ahead.

In regard to the drilling of the property, I can say that it was all done before my connection with the company, and the records were in such shape that I considered them, in the main, unreliable. It is common sense and a well known fact that ground, considered for mining purposes, should be thoroughly drilled or otherwise explored before commencing mining operations, and the writer of the article should know from his professional experience that it would be absolutely impossible to verify the drilling and correct all the mistakes in the short time I had been on the ground. As long as the dredge was there, my hope lay in the machine at least proving the ground and showing results which would induce my people to properly drill the remaining holdings, and take means to correct the errors that were so apparent.

I wish to state that the writer of this letter is a graduate of a reputable mining school, has been employed for 17 years by people connected with the greatest mining enterprises of this, or any other country, and if the author of the article in question cares, or will take pains to inquire from some of the principals connected with these enterprises, regarding the writer's standing, he will no doubt ascertain whether he would be considered capable of managing the affairs of a dredging concern.
In writing a paper like the one under discussion, based, evidently, largely on information obtained from irresponsible persons, the author descends to the plane of the ordinary mining reporter of our local papers. I know of no code of professional ethics which would commend the unwarranted and cynical criticism of Mr. Rickard's article.

W. W. J. Croze.

Duluth, December 7.

[We are glad to give Mr. Croze an opportunity to defend himself; we are not surprised at his annoyance. In explaining some of the causes of the disaster to the Bourbon Creek dredge, he thinks it necessary to attack his critic; this also is natural. But he is in error in regard to the manner in which the information was obtained; the author of the article made not one visit of 10 minutes, but three different visits aggregating two hours, at least, and these visits to the dredge were supplemented by lengthy conversations with Dr. Cabell Whitehead, one of the directors, besides an interview with Mr. E. L. Smith, the constructing engineer, and others likely to know the facts. To Mr. Croze the author of the article was introduced as the editor of a technical journal in search of reliable information concerning the local mining industry, and if he was so unwise as not to use the opportunity to explain the disastrous condition of the dredge, it was not the fault of the author, who questioned him courteously on several other matters. Mr. Croze made the mistake of taking charge of a mining operation for which his previous experience afforded no preparation; he was the victim of circumstances some of which were beyond his control and some beyond his ken. While regretting to have hurt the feelings of any man, the author of the article thought it well to emphasize the blunders made by the Nome Mining Co. upon its Bourbon Creek dredge so that others might be warned from sharing the misadventures of Mr. Croze and his directors.—Err.]

Eucalyptus for Mine Timbers.

The Editor:

Sir—The recent discussion in your paper on the value of eucalyptus for mine timbers by Messrs. A. H. Martin and T. L. Carter is of particular interest to me, and it should be interesting to everyone engaged in mining. Having made a special study of the eucalyptus, with reference to its suitability for railroad ties and bridge timbers, where hardness, strength, and durability are wanted, I feel that Mr. Carter's letter should not go unanswered. The mining industry is as much concerned in the future supply of timber as the railroads. I agree with Mr. Martin's statements, with a few exceptions.

The woods of the eucalyptus are heavy, only a few species floating in water. According to McClatchie, there are 22 species cultivated in the United States that are suitable for railroad ties and underground work. Selection of species with reference to use as timber must be considered in relation to soil and climatic requirements.

To the average person, the term 'eucalyptus' has meant nothing but the most widely planted species, Eucalyptus globulus, or 'blue gum.' In Australia several species are known as 'blue gums' and several as 'red gums'; and the same species may be designated by several different common names. Australian common names that have been generally adopted in America are 'blue gum tree' for Eucalyptus globulus, and 'red gum tree' for Eucalyptus rostrata and several other species indiscriminately. The entire genus Eucalyptus should not be condemned because the wood of one species, according to Mr. Carter, has been found inferior to other timbers for mining purposes.

The principal drawback to eucalyptus timber has been its tendency to check, or open fissures and shakes, and its hardnes, with consequent difficulty in spiking and working. The better understanding of methods for seasoning and handling this timber is doing much for its advancement. Mr. Carter has considered only Eucalyptus globulus, and has hardly given that widely known species its due. Its timber is hard, heavy, strong, and fairly durable. In America, however, it is not considered equal in timber properties to the ironbarks, to the sugar gum, or to the red gums. Its fast-growing characteristic has been its chief claim for prominence, and has led to planting in different parts of the Southwest for windbreaks and fuel.

For mine-timbering, there are other species that are superior to the blue gum. There are about 17 species of eucalyptus that could be grown by mining companies and would furnish satisfactory material for timbering. According to the report of the State Board of Forestry, blue and sugar gum timber have been used with success in timbering mines near Escalante that are flooded during a part of each year.

The sugar gum (Eucalyptus corynocalyx), the red gum (Eucalyptus rostrata), and the narrow-leaved ironbark (Eucalyptus crebra) are eucalyptus that should recommend themselves to the mining industry. The durability, hardness, and strength of the timber obtained from these species make them eminently fit for the mines. The sugar gum furnishes a wood that is very durable as railway ties, as posts, and for underground use. Baron von Mueller states that posts set in the ground 15 years showed no signs of decay. The wood warps but little in drying, and when dry is very hard. In the interior valleys of southern California and Arizona it withstands both the intense heat of summer and the frost of winter. For desert country this is one of the most eligible among timber eucalyptus. It does not grow quite as rapidly as the blue gum, but furnishes a more valuable timber. In New South Wales the ironbark is considered the king of hardwoods. The narrow-leaved ironbark endures a greater variety of climatic conditions than do other ironbarks. At Fresno, California, it grows vigorously, and young trees have grown well near Phoenix, Arizona. It is said to be content with poor soil, and, judging by experience with it thus far, it ought to grow in most valley and hillside situations in the Southwest.

An important point in considering the value of commercial plantations of eucalyptus has been deter-
MINING AND SCIENTIFIC PRESS

December 26, 1908.

mined by the United States Forest Service, from strength tests made by them, namely, that the fastest growing species are also the strongest. The bending tests showed the modulus of rupture in pounds per square inch to be:

<table>
<thead>
<tr>
<th>Age in Years</th>
<th>Pounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sugar gum</td>
<td>15, 25,344</td>
</tr>
<tr>
<td>Blue gum</td>
<td>30, 22,265</td>
</tr>
<tr>
<td>Blue gum</td>
<td>15, 16,900</td>
</tr>
<tr>
<td>Red gum</td>
<td>15, 14,350</td>
</tr>
</tbody>
</table>

The crushing strength in pounds per square inch, the compression being parallel to the grain, was:

<table>
<thead>
<tr>
<th>Age in Years</th>
<th>Pounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sugar gum</td>
<td>15, 11,290</td>
</tr>
<tr>
<td>Blue gum</td>
<td>30, 12,310</td>
</tr>
<tr>
<td>Blue gum</td>
<td>15, 8,190</td>
</tr>
<tr>
<td>Red gum</td>
<td>15, 7,725</td>
</tr>
</tbody>
</table>

The crushing strength of some American woods, in pounds per square inch (from Kidder):

<table>
<thead>
<tr>
<th>Species</th>
<th>Pounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oregon pine</td>
<td>4,500</td>
</tr>
<tr>
<td>California redwood</td>
<td>3,000</td>
</tr>
<tr>
<td>White pine</td>
<td>2,500</td>
</tr>
<tr>
<td>White oak</td>
<td>4,000</td>
</tr>
</tbody>
</table>

Comparison with Forest Service tests on hickory shows that 30-year blue gum is stronger than XXX hickory, and that 15-year sugar gum is nearly as strong as second-growth hickory. These tests would seem to disprove Mr. Carter's statement that the blue gum wood is of poor quality, and not strong enough for props in heavy ground. Perhaps the timber was not properly seasoned, or from immature trees. We see from the above tests the difference in strength between 15 and 30-year blue gums.

I believe mining companies would do well to plant eucalyptus for their future supply of mine timbers, not necessarily at the mine, but in the nearest locality available for a commercial plantation. A careful selection of species suitable for this work and a thorough investigation of local climatic conditions, by someone familiar with the requirements and cultivation of eucalyptus, may save money and avoid failures.

Leslie W. Symmes.

San Francisco, December 7.

Dredging on the Seward Peninsula.

The Editor:

Sir—The article in your issue of November 28, entitled 'Dredging on the Seward Peninsula,' recalls certain facts in connection with the construction of the Three Friends dredge on the Solomon river.

The contract for this dredge was not let until toward the end of December 1904. The machinery was furnished by the Bueyurus company of Milwaukee, while the hull was built and the machinery installed by the Western Engineering & Construction Co. of this city. The plan followed by the contractors was as follows: All the lumber used in the construction of the hull, and for the support of machinery, was framed and made ready, as far as possible, for placing in position, before being shipped north. While this work was being carried forward at Seattle, the machinery, supplies, and everything else necessary for a complete dredge were being assembled at that port. In the early part of June 1905 the entire outfit was loaded on one vessel and started on its long journey to the Solomon river. The framing of timbers, assembling of machinery, together with the equipment and loading, were under the personal supervision of D. P. Cameron and E. E. McCarthy, the latter now in charge of the dredges of the Yukon Gold Co. at Dawson. Both men were then connected with the Western Engineering company. The construction crew, composed of men experienced in dredge-building, went north on the steamer that carried the lumber and machinery. McCarthy was in command of the party and superintended the construction. The plan of "putting all your eggs in one basket" was a good one, for it insured having everything necessary for the work at hand, as needed. It was not all plain sailing, however, for shortly after the cargo had been unloaded on the exposed shore, near the mouth of the river, one of the storms for which Bering Sea is noted arose, and in a few hours the beach for several miles was strewn with dredge-timbers, while some of the machinery was buried in sand cast up by the waves. Undaunted by this misfortune, W. L. Land, one of the owners, assisted by the construction crew, re-assembled all the parts and materials, and by working night and day the dredge was completed so that digging operations commenced early in September. A successful run lasting 35 days was made, when the advent of cold weather forced a suspension of operations. It was found that everything necessary for the work had been provided, and to this, and to the energy and ability of those in charge of the work, can be attributed the success of the undertaking. It must be a source of great satisfaction to those who accomplished this task, to know that the dredge has 'made good.' The experience of the Three Friends company affords ample proof that a modern gold dredge can be constructed expeditiously and operated profitably in the far north when the management is what it should be.

R. F. Lewis.

San Francisco, December 12.

This is an interesting note and we are glad to publish it. Of Mr. McCarthy's energetic work we have heard from Dawson and from Nome. He deserves credit, so does Mr. Cameron. Another item of credit remains to be allocated: we refer to the Bueyurus company. The author of the article containing the description of the Three Friends dredge wrote with approval, indeed with enthusiasm, concerning the good sense and skill exhibited in this dredging enterprise and he pointed to it as a model. At the time of writing the article he did not know who manufactured the machinery, although he had noticed the excellence of it. But now that the matter has been mentioned, the author is only too happy to state that the Bueyurus company supplied the machinery on the Three Friends dredge and, what is more, their delivery of that machinery was so prompt and so complete as to have been an important factor in expediting the construction.—Boron.
CALUMET & HECLA COSTS.—II.
Written for the MINING AND SCIENTIFIC PRESS
By L. S. Austin.

The Buffalo smelter of the Calumet & Hecla Mining Co. receives No. 1 and No. 2 C. & H. ‘mineral’ and anodes from the smelter at Hubbell, anodes from the Quincy smelter at Hancock, and Adventure anodes made at the same place. Anodes weigh 400 lb. each and are of 2 in. average thickness. They are set with stripping-sheets to start the cathodes, the cathodes being withdrawn when the anode is half dissolved and a fresh stripping-sheet inserted to take the rest of it. In other words, the cathodes are twice drawn for each anode.

The cathodes have a conductivity of 101.5%, Mathessen standard, and will be found to contain 99.98% copper. The electrolytic works at Buffalo cost $200,000.

The No. 1 mineral shipped to Buffalo is melted in charges of 40,000 and 100,000 lb. with 29 to 60% cathodes, to give a product of refined copper having an average conductivity of 100%. The following shows the quantities of No. 1 refined copper and of electrolytic thus combined:

<table>
<thead>
<tr>

</tbody>
</table>

14,959,878 9,916,547 24,876,426

About one half of the product of the Calumet & Hecla is treated at the Buffalo works, and it may be inferred that the charges will contain on an average 40% of anodes for that period. It will be seen that some twenty million pounds of copper was produced annually as anodes, the output being very regular, while the quantity of No. 1 mineral is variable, during the period 1905-06 the proportion of anodes was but 35% of the total charge. At this time the quantity of ‘mineral’ was larger than at the second period (1906-07), and the excess was added to the larger furnace (No. 4), where the proportion of anodes was but 23%. The percentage varied greatly at times, apparently according to the supply immediately available; three charges contained mineral only, and had a conductivity of 99.3%; six charges consisted of cathodes only and had an average conductivity of 101.5%. Of the last, four were made into wire-bars.

The output of the Hubbell smelter for the fiscal year 1906-07 may be given at 72,000,000 lb.; that of the Buffalo works from No. 1 mineral of 80% copper at 20,000,000 lb. of refined product.

In reference to the slag from this product sent to the cupola to be made into blocks, its quantity must have been small, and it would naturally be put into a reverberatory furnace on Saturday, allowed to stand over Sunday, and thus by the continuous treatment eliminate the arsenic. The products of the three furnaces are marked C. & H., and are put on the market at the same price as the output of the Hubbell smelter.

The conductivity tests go to show the uniform excellence of the product of the Buffalo works, all most all being such that it could be used for wire-bars. The minimum was 98.95% in one instance, the highest 101.9. Besides the anodes made from the No. 2 mineral at the Hubbell works, anodes from the Quincy and from the Adventure mines are treated.

For the year ending April 30, 1906, the total ‘mineral’ treated at the Hubbell works was 46,000 tons; the expenses being as follows:

- Total smelter expenses: $355,842
- For new construction: 22,290

Leaving for operating expense: $333,551

Which, on 46,000 tons, figures $7.23 per ton.

The total mineral treated in the year ending April 30, 1907, was 43,000 tons; the total expenses for doing being as follows:

- Total smelter expenses: $462,000
- For new construction: 156,900

Leaving for operating expense: $306,100

Which, on 43,000 tons, equals $6.5578 per ton of mineral smelted. The figure per ton of refined copper was $11.78, so that the average of the mineral was 59% copper.

The items of operating expense are:
- Supplies, including ladies, brick, fire-tools, iron and steel, coal, coke, sand, limestone, poles, etc.
- Labor, including all engaged in the actual smelting and outside hands about the yard.
- Laboratory expense.
- Machine-shop expense.

General expense, including salaries of superintendent, office-men, but no portion of the expenses of the Boston office.

Repairs for existing plant.

Taxes.

No allowance was made in the above for depreciation, interest, or insurance (the company assuming its own risk on the latter), nor for new construction.

On the basis of the figures given above we may estimate the silver recovered from No. 2 C. & H. mineral at 100,000 to 130,000 oz., worth, at 60 cents per ounce, $60,000 to $84,000.

The costs at the C. & H. works at Buffalo for treating anodes, including the re-melting of the cathodes produced, is given at $8.497 per ton of refined copper. This includes, besides prime costs, general expenses and the cost of recovering and marketing the silver contained in the anodes. The value of this silver, which may be variously estimated at from 10 to 14 oz. per ton of cathodes, is, at the highest price, in 1906, sufficient to meet the above-mentioned expense of electrolytic treatment.

The cost of re-melting was stated at $4 per ton, leaving $4.50 per ton for electrolytic refining proper.

The freight on mineral from the mill at Lake Linden to Buffalo is 85 cents per ton.

We may compute the expense of treating No. 2 mineral of 20% copper as follows, per pound of copper obtained:

| Reverbatory melting of No. 2 mineral | $ 7.10 |
| Smelting slag to produce cupola blocks | 4.24 |
| 400 lb. copper at 28.35c. | $11.54 |
We have accordingly the costs per pound of copper:

<table>
<thead>
<tr>
<th>Description</th>
<th>Cost (cents)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Producing cupola blocks</td>
<td>2.335</td>
</tr>
<tr>
<td>Re-melting cupola blocks, $4 per ton</td>
<td>0.200</td>
</tr>
<tr>
<td>Shipment to Buffalo, $6c. per ton</td>
<td>0.011</td>
</tr>
<tr>
<td>Electrolytic refining, $8.50 per ton</td>
<td>0.450</td>
</tr>
</tbody>
</table>

Costs per pound of copper: 3.526

From the testimony brought out in the litigation, we obtain the following comparative selling expenses and prices obtained per pound for copper by the respective companies in the year 1906:

<table>
<thead>
<tr>
<th>Company</th>
<th>Expenses (cents per pound)</th>
<th>Net price (cents per pound)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calumet &amp; Hecla, Osceola</td>
<td>5.89</td>
<td>5.54</td>
</tr>
</tbody>
</table>

In the testimony against the Calumet & Hecla Mining Co. it appears that some 10,000 short tons of copper are treated by electrolysis that contain 10 to 14 oz. silver per ton, that is, 100,000 to 140,000 oz. silver, worth $30,000 to $70,000. No mention of this asset or product of the company is made in its annual report. The same practice is followed by other companies producing Lake copper. Formerly, before the time of electrolytic refining, this could be justified because the silver could not then profitably recovered. Even now, unless the copper contains 25 to 30 oz. silver, it is supposed only to pay for its removal. With silver worth 60c. per ounce, 10 to 14 oz. silver in the anode-copper would repay the cost of refining by electrolysis, and all over this should be a profit, and should be specified in the annual report. Incidentally, such refining greatly improves the quality of casting copper or of blister copper to bring it on a par with the best of Lake copper, so that it could be sold as such. Western copper-producing companies take account of the gold and silver contained in their blister copper, and figure it as an asset of the company. Thus, the Utah Consolidated Copper Co. in 1905 had an average ore of 3% copper, with 1.3 oz. silver, and 0.10 oz. gold per ton. This, without allowing for treatment losses, would result in a blister copper of 40 oz. silver and 3 oz. gold per ton. Here the precious-metal values are certainly important. The Utah Consolidated report thus gives the cost of producing copper at 5c. per pound; allowing for the precious-metal values, the cost becomes 5c. per pound of copper produced.

A wireless telegraph system in which the direction of the messages is under control has been devised by Bellini and Tosi, and tested under aid given by the French government. The result has been secured by means of two rectangular aerials fixed at right angles and so attached to the apparatus for reception and transmission as to permit the transmission of unequal currents. These two electro-magnetic forces unite and produce an electro-magnetic field, and the Hertzian waves are projected in a single vertical plane, which can be alternated instantly by means of the Bobine device.

WICHITA MOUNTAINS, OKLAHOMA.

Written for the Mining and Scientific Press
By G. W. Keesly.

In 1904 eight mining districts were active. Today work is being done in only three localities. Within a radius of two miles from Wildman a number of prospects are being worked intermittently. South-east of Snyder, on Deep Red creek, washing of gravel for gold is being done. North and northwest of Cache several shafts are being sunk and one or two tunnels are being driven.

The town of Wildman consists of a settlement of about 70 persons. The country rock is a gabbro, cut by numerous dikes of aplite. In places the gabbro has the character of a diabase; in this phase segregations of a hornblendic type occur that look like hornblende dikes. These have been mistaken for veins, and considerable work has been done in prospecting along such formations. The action of water on the gabbro has formed a chloritic mineral, which prospectors have supposed to be due to copper.

Shafts have been sunk. Ore containing chrysocolla, the copper silicate, occurs in small quantities. Quartz containing gold and silver occurs in a few of the mines, but the ore is not much mineralized, although the owners claim assays as high as $100 per ton. The only shaft that is more than a prospect hole is the Baby. This has a depth of 85 ft., and from it ore running $32 per ton is claimed to have been taken. On a number of other prospects the assessment work is being done each year, but no systematic mining is evident.

No mining is being done in the Snyder district at present, but south and east of the town of Snyder a company is working a placer. The gravel fills the bottom of a small stream. It seems to be a disintegrated conglomerate formed from the erosion of the granite mountains to the north. The gravel is shored into a sluice-box by hand and run down a distance of about 200 ft.; it is screened three times, the larger rocks thrown out each time.

North and northwest of Cache a number of prospects have been started. The country rock is a granite filled with minute vugs containing limonite. Dikes of fine-grained porphyry are present, but are not as common as in the Raggedy mountains around Wildman. The ore shows galena and zinc-blende.
ORIGIN OF COBALT-SILVER ORES OF ONTARIO.

By REGINALD E. HORE.

The rapidly increasing proved area of silver and cobalt-bearing rocks of northern Ontario has disclosed new types of deposits, and has afforded additional information regarding the origin of the deposits of the rocks containing them.

The majority of shipping mines are situated in the eastern half of Coleman township, and are therefore within a few miles of the town of Cobalt. The producing veins occur in graywacke and feldspathic quartzites and conglomerates of Lower Huronian age, in metamorphosed, fine-grained, green-colored igneous rocks of Keewatin age, and in gray diabase-gabbro sills of Post-middle Huronian. In the Huronian sediments and in the diabase, the veins are nearly vertical, while in the Keewatin greenstones the inclination is irregular and the veins are less well defined. W. G. Miller suggested that the fissures now occupied by the cobalt-silver ores in the Lower Huronian were probably formed by the disturbance which accompanied the eruption of the diabase and gabbro, and that the ores may have been deposited from highly heated mineral-laden waters, associated with the eruption. In a second edition of this report he has suggested that the ores were possibly leached from the Keewatin greenstones, or from the Laurentian granites. Van Hise also concludes that the diabase is the source of the ore, and believes that the Keewatin and the conglomerate are the maui source of the calcite of the gangue minerals. He suggests that the solutions bearing calcium carbonate were a factor in the precipitation of the metalliferous minerals. A consideration of later discoveries seems, in large measure, to confirm the truth of these ideas.

Cobalt is now known to occur in several areas, as follows: in Lower Huronian graywacke, in Casey township, 15 miles north of Cobalt; in diabase-gabbro, in Peuse and Ingram townships, 30 miles north of Cobalt; in Whitson and adjoining townships; 25 miles west of Cobalt; in James and adjoining townships, 15 miles north of Whitson; in the vicinity of Portage bay, of Trout lake, and west of Animas Nipissing lake; and in Keewatin rocks, south of Lorrain township, 16 miles southeast of Cobalt.

The detection by the naked eye of scattered smaltite crystals in the diabase, suggests the possibility of its being an original constituent in the rock. On the other hand, the association with aplite suggests that the ore had its origin in the solutions that accompanied these intrusions. Microscopic examination shows that the smaltite is of secondary origin. Accordingly the following conclusions may be drawn: (1) That the smaltite was introduced by solutions associated with the aplite intrusion; (2) that such solutions came after the crystallization of the aplite; (3) that the intrusion disturbed the diabase to such an extent that a zone was formed in the latter which was more permeable to the solutions than was the aplite itself; (4) that these solutions had little action on the feldspars, but found other silicates quite active chemically. Further conclusions may be deduced from a consideration of the origin of the aplite.

The most evident difference between the aplite and the diabase is the color. This is due to a higher percentage of quartz and of alkali-feldspars, and a correspondingly lower percentage of dark-colored silicates, so that the aplite is generally light pink in color, while the diabase is dark gray. Portions of the diabase sill at some distance from the edge are coarse in texture and sometimes pink in color. Here again the difference in color is due to a greater development of quartz and less augite. The distance from the edge of the sheet, and the coarse texture show that these more silicious portions have crystalized later than the main mass. This shows that differentiation has taken place in such a way that the melt has become more silicious, possibly approaching a eutectic mixture. These pink coarse-textured portions have a mineralogical composition intermediate between that of the gray portion and that of the more silicious aplite. From the composition and the field relations it is thought therefore that the aplite is a later secretion from the further differentiated diabase magma. The relation of the aplite to the diabase is similar to that of contemporaneous veins in rocks described by Waller and Teall. It is thought justifiable therefore to apply this term to the aplite occurrences.

It has been shown that the ores were deposited from solutions which followed the aplite intrusions. The origin of these solutions cannot be proved, but the association with aplite suggests a genetic connection. It seems that as the diabase magma cooled and crystallized the melt was approaching a eutectic of predominating silicic composition. If water and metallic sulphides and arsenides were being concentrated, this was probably by the formation of a solution whose constituents were not soluble in all proportions in the silicate solution. The former solution was not miscible with the latter, and remained liquid or gaseous after temperatures had been reached at which the latter had solidified. When fractures in the diabase provided means of escape, part of the metalliferous solution doubtless accompanied the aplite solution, and, as has been shown above, part escaped subsequent to the aplite deposition. That such a deposit is due to extreme differentiation in the igneous magma, is in harmony with the expressed views of J. E. Spurr regarding the origin of most metalliferous deposits. While no silver was found in the rock-sections examined, the occurrence of native silver with cobalt minerals in aplite in James and adjoining townships, indicates a similar origin for the silver. While it has been shown that in the veins at Cobalt silver solidified

---

A clearer idea of the part played by the intruded rocks is to be obtained by a study of the character of the Keewatin and Huronian formations over the wide area in which cobaltiferous diabase is now known to occur. In Coleman township this formation is represented by igneous rocks only. Perhaps the most abundant type is a fine-grained green rock in which there is considerable chlorite and calcite, and still undecomposed remnants of augite. There are also intrusions of coarser-textured rocks which appear to be altered gabbros and diabases. In Casey township is an outcrop of a dark green, fine-grained rock which appears to be an altered basalt, and in Tudhope township a coarse-textured greenstone intruded by Laurentian granite was observed. In other areas sedimentary rocks are associated with those of igneous character. At Larder lake occur auriferous cherty carbonates, while at Temagami there are carbonates and cherty iron ores. A study of Miller's map shows that none of the veins of economic importance are situated more than a few hundred feet away from the igneous Keewatin rocks. Equally significant is the fact that in areas in which the latter are not found, the cobalt-silver deposits are less extensive, and many cobaltiferous veins contain no native silver. As Van Hise has indicated, these rocks contain a considerable percentage of calcite, which furnished the gangue. It is also to be noted that there are present many relatively unstable minerals, such as pyroxene, hornblende, and biotite, that are readily acted upon by percolating waters. These minerals are active chemical agents, and doubtless by their reactions with ore-bearing solutions aided in the precipitation of the ores. From the field study it seems beyond doubt that such has been the case.

The lower Huronian is represented by graywacke slate, feldspathic quartzite or arkose, and graywacke conglomerate, in ascending order. The strata have, as a general rule, been but slightly disturbed from their original position; but in some places are inclined as much as 45°. Their character has apparently been but little changed by igneous or dynamic metamorphism, except at the immediate border of the diabase where some hardening has taken place by a re-crystallization of quartz.

Bell's describes the conglomerate as a volcanic breccia. Miller suggests that "some of the delicately banded graywacke-slate may represent volcanic dust or fine-grained pyroclastic material," but that the lower conglomerate is not pyroclastic and is made up of fragments of the adjacent older series. The examination of thin sections of graywacke shows an

'Robert Bell, 'The Cobalt Mining District,' Journal Canadian Mining Institute, 1907, p. 64."
absence of glass or mineral fragments characteristic of volcanic dust. The chemical analysis shows it to be of a composition similar to an ordinary Paleozoic shale.

\end{array}
\]

(A) is a composite analysis of 51 Paleozoic shales, by H. N. Stokes, of the U. S. Geologic Survey.

(B) is the analysis of graywacke slate from the Little Silver mine, made by A. G. Burrows, of the Ontario Bureau of Mines.

The writer concludes therefore, (1) that there was no volcanic activity contemporaneous with the Lower Huronian, (2) that these rocks were formed entirely of the detritus of the Laurentian and Keewatin formations, (3) that the arkoses, at least, are primarily of Laurentian origin.

Attention has already been drawn to the fact that the feldspars were but slightly, if at all, altered by the ore-bearing solutions. Chalcopyrite, sericite, and quartz are well known to be stable minerals, and it therefore follows that the arkoses cannot have been active agents in depositing ores. The graywacke is made up of similar minerals with a larger percentage of secondary products. Calcite is sometimes present in small amounts, and it is noteworthy that these rocks show a marked deficiency in lime, as compared with the Keewatin. It is thought, therefore, that while the Keewatin greenstones have probably, by virtue of their mineralogical composition, played an important rôle in the deposition of the ores, the graywacke, being composed of more stable minerals and low in caliche, played the same rôle in a minor way, if it all. The pebbles in the conglomerate contain numerous primary ferro-magnesian minerals which would be readily decomposed, and so the coarse conglomerate may have been more active than the graywacke slate. Owing to their regular vertical jointing, these sediments have afforded the most suitable place for the deposition of the ore, and so it happens that many of the most valuable veins have been found in them.

Miller has pointed out that marked changes in silver content take place in passing from conglomerate to the Keewatin rocks. Considerable silver is being mined from the latter; but it has in most cases been found that the veins are not so regular as in the overlying shell of conglomerate. The lower limit of the deposits has not yet been determined. There are no borings of more than a few hundred feet, and it is consequently not known whether there is another diabase sill at a lower horizon. Solutions from a lower sill would find in the intruded Keewatin an agent which assists in deposition; but there can be no repetition of the Huronian sediments.

In conclusion it may be said that it has been shown that the stokes of the ore have been deposited from solutions which followed the formation of veins of aplitic in the diabase. Owing to the fact that in all the silver deposits in the district the silver minerals are intimately associated with cobalt minerals, the silver is believed to have the same origin. It is suggested that the metallic sulphides and arsenides have been concentrated from the diabase magma by extreme differentiation. The Keewatin igneous rocks have assisted in the ore-deposition on account of their content of calcite and unstable minerals. The Huronian sediments are composed for the most part of stable minerals with little calcite, and their chief function has been that of a recipient for the ores. If these conclusions are correct, we may expect to find similar ore deposits where the diabase sills are associated with Keewatin igneous rocks, and especially valuable deposits where Huronian sediments are also present. The region from Lake Temiskaming to Lake Huron doubtless includes many such occurrences.

**RELATION OF COPPER TO PYRITE IN BUTTE ORES.**

In an article contributed to *Economic Geology* (Vol. III, No. 7), James F. Simpson details the results of applying the system of rock-study known as 'metallo-graphy' to the lead copper ores at Butte, Montana. This method, introduced by William Campbell and C. W. Knight at the Columbia School of Mines, New York, consists in dressing a chip of the rock or ore, about one inch square, by the usual methods, finishing the polish on plate glass with rouge. This surface is then examined by a microscope with reflected light, and from the color and solubility when treated with various solvents, chiefly acids, the opaque minerals present are identified. Quantitative determinations may be made by micro-measurement of the etched faces corresponding to the several minerals present. From Mr. Simpson's studies he reached the following conclusions, four facts standing out clearly:

1. Copper minerals can be detected microscopically in all the samples where chemical analysis reveals copper.

2. The copper minerals thus present within or associated with the pyrite are chalcopyrite, bornite, chalcocryptite, and enargite.

3. The order of deposition of these minerals in the ore is: chalcopyrite, enargite and bornite, chalcocite. The enargite and bornite are closely associated, and from the specimens at hand the exact order of deposition of these two could not be determined.

4. Copper is absent from specimens containing no copper sulphide minerals. Therefore the copper is not present in chemical combination with the pyrite of the lean Butte ores, but on the contrary, it is present intimately associated with the pyrite in definite copper minerals of four kinds (chalcoite, bornite, chalcocryptite, and enargite), and these minerals occur in a definite order.

The samples used were selected from the copper mines at Butte. Only those that showed no copper mineral to the naked eye were used, for it was desired to find the relation of the copper to the pyrite in those ores in which the existence of definite copper minerals was unknown. It would, of course, be desirable to know whether the samples used represented ores of primary deposition, or ores largely produced by secondary enrichment.
CUSHIONING VIBRATIONS OF CAM-SHAFTS.

Written for the Mining and Scientific Press
By Aldegan Del Mar.

The vibrations in a stamp-mill are caused by the impact of the falling stamp on the ore between the die and the shoe, and those set up in the camshaft when the cams strike the tappets in the act of raising the stamps. The vibrations due to the falling stamps are cushioned to a certain extent by the layer of ore on the die and are confined to the stem and mortar-block and are necessary in this type of machine. The vibrations of the cam-shaft are very disagreeable. They cause nuts to loosen, bolts to break, cam-shafts to crystallize, cam-shaft bearings to wear out, and so occasion a loss of power. No attempt has thus far been made to cushion these vibrations.

The drawings herewith shown represent a design I have made to lessen these vibrations and incidentally to afford the mill-man a means of alternating the drop of the stamps without touching the tappets. The proper material for cushions, which will be 8 in. square, is yet a subject for experiment. Pieces of thick belting may serve well. When it is required to lower the stamps, pieces of this material may be taken out and replaced at will. An opening is provided in the front of the chair for this purpose. The daps or gain in the battery post on which the chair sets may be cut in an inch or two and filled with some cushioning material for the cam-shaft bearing, which fits in the chair, but does not touch the chair except on the sides, the bottom of the chair being open. The collars on the shaft should be of sufficient diameter to always bear on the sides of the chair. The lip F on the bearing, which may be called the plug, will keep the grease where it will fall into the receptacle D on the chair, or cotton waste may be used to catch it. The plug is shown solid, but this is not necessary. Manufacturers of stamp-mills should do something to alleviate the miseries of the cam-shaft floor, and these drawings are submitted in hope that the subject may be taken up.

Difference of Style.—In making allowance for the Kaiser's uttered indiscretions, we must remember the German language. Ordinary German prose suffers from a dreadful excess of metaphor. The "unailed fist" and the "loosened sabre" are not altogether rhetorical sparks struck out on the hot anvil of Imperial excitement, but examples of that poetic exaggeration so easy to a German. It is a fault most common among the most learned. Professor Jones, of Yale or Harvard, would probably begin his volume on The Geology of Yucatan: "By Yucatan, in the present work, I mean the Central American peninsula known by that name as well as the adjacent coasts," etc. But Professor Hammerschlag, of Leipzig, must begin by saying: "The convulsive, continent-splitting efforts of Terra—or perhaps Gia—to pour forth her imprisoned vital forces brought forth, in the dim Triassic ages, the torrid land-mass which lolls like a sleeping monster between the warm waters of the Caribbean and the torrid waves of the Gulf of Mexico in 87 to 92° west longitude." An English politician speaking in English says: "This country—or—welcomes the—is—friendly rivalry of a great power like Germany under its—is—honored sovereign as—is—conducive to the interests of both nations," etc. But when a German statesman rises to speak, the genius of his language demands that he shall say: "Germany wants peace, but she will continue to stare defiantly into the blood-shot eyes of ravening naval powers who with eager claws," etc.—The Evening Post, New York.

Fractionation of crude petroleum by capillary diffusion was suggested to David T. Day by the refining of black vaseline by filtering it through warm, dry, fuller's earth. Experiments conducted by the U. S. Geological Survey showed that when petroleum is allowed to rise in a tube packed with fuller's earth there is a decided fractionation of the oil, the fraction at the top of the tube being of lower specific gravity than that at the bottom. When water is added to fuller's earth which contains petroleum, the oil which is displaced first differs in specific gravity from that which is displaced afterward, when more water is added. When petroleum is allowed to rise in a tube packed with fuller's earth the paraffine hydrocarbons tend to collect in the lightest fraction at the top of the tube and the unsaturated hydrocarbons at the bottom. When oil is mixed with fuller's earth and then displaced with water, about one-third of the oil remains in the earth.
THE KOSAN MINE, KOREA.

By A. D. Weigall.

Kosan is the Japanese pronunciation of the Chinese characters forming the Korean word Kapsan. The mine is situated at the small village of Ko Djin Dong, 23 miles east of the walled city of Kapsan, in the province of Ham Kyun, in northeast Korea. The distance from the nearest seaport is about 130 miles by road, and the question of transport presents some difficulty, but otherwise the local conditions are good, there being an abundance of excellent timber around the mine; water-power and cheap labor are also obtainable in abundance. The climate is cold, but dry and healthy; the elevation of the mine is 5000 ft. above sea-level.

The mine has been worked continuously for the last 25 years. Three years ago the mine was producing per annum 300,000 lb. metallic copper. At present the output is between 400,000 and 450,000 lb. This copper is mainly purchased by the Japanese and shipped to Japan from the Korean port of Gensan. A small amount of the copper is consumed locally in the manufacture of brass, of which all Korean household utensils are made. Kapsan was one of the mines held as private property by the Korean Emperor, and it is believed to have yielded him a large income, though no figures are available. The mine is well known, and is generally regarded as the most valuable mine in Korea. However, the Koreans had always succeeded in preventing foreigners from examining or securing any interest in it until just before the Russo-Japanese war, when the Korean Emperor granted a concession to the American firm of Collbran & Bostwick, giving them the mine. During the war the Japanese prevented any examination being made, but on the day after peace was signed I left Seoul, accompanied by my assistant, A. H. Collbran, and succeeded in reaching the mine in October, 1905, without being stopped by Japanese troops. This was the first time any white man had seen this mine, though during the war a party of Japanese engineers had examined it.

Knowing the great value of the mine, the Japanese made every effort to secure possession of it, and for three years the Japanese Government has opposed Messrs. Collbran and Bostwick's claim. The American Government, however, strongly supported this firm's undoubted rights, and in June of this year finally caused the mine to be transferred to them. I am leaving Seoul in two days time, with an engineering party, to start work at the mines, and we hope by next spring to have the development well under way. The mine at present is only opened up in the slovenly Korean manner, and practically no reserves are blocked out. It, however, presents great promise of being developed into a large producer within the next two or three years.

The Koreans mined and smelted the ore in a most primitive fashion, partly roasting in stulls and smelting in small circular clay furnaces, using charcoal for fuel, draught being produced by a Chinese windbox. The ore is practically self-fluxing, a basic slag being produced containing 23% silica and 2% copper. This slag is run into pits dug close to the furnaces, and there must be many thousand tons of it buried at the mine. The metallic copper produced has an average composition as follows: copper, 98.02%; gold, 3.2 dwt., and silver, 2.24 oz. per ton of copper.

The deposit consists of large irregular bodies of massive sulphides, occurring in a highly metamorphosed limestone of Paleozoic age. The orebodies roughly follow the dip of the limestone, replacing it along the stratification. The deposits are found in the neighborhood of intrusions of diabase or gabbro, with which their origin is undoubtedly connected, and the formation comes under the head of metasomatic deposits. The boundaries of ore and limestone are sharply defined. The ore consists of a mixture of chalcopyrite, arsenopyrite, and iron pyrite, without any gangue or contact minerals. Its average composition is as follows:

<table>

The appearance of the ore shows rounded grains of iron pyrite surrounded by copper sulphides, leading to the conclusion that there has been some alteration of the original ore, which must have mainly consisted of iron pyrite. Near the surface the ore was composed of various oxidized copper minerals. I obtained a specimen, about 3 by 1 in., of native copper from one of the miners, who informed me that in the early days of the mine such specimens were not uncommon. Much of the surrounding country to the north of the mine is covered with a surface flow of basalt, which came from the well known Paik Tu San (Ever White mountain), the extinct crater of which is now a lake, forming the source of the Yalu river.

Besides the Kapsan mine, there is another copper deposit of less importance in North Pyeng Yang province, near the town of Hu Chang. This property had been formerly worked by Koreans, but it has been shut down for some years. Other than the two above mentioned properties there are at present no copper deposits in Korea that show promise of being developed into important producers, though copper is found in many parts, particularly in the south, mostly as small and narrow quartz veins, sometimes high-grade in copper.

While on the question of copper mines, you will probably be interested to hear something of a mine at Tien Pao Shan, in southeast Kirin province, in Wen Chun district, about 80 miles north of the Korean frontier, on about Lat. 43° N. and Long. 129° E. This mine has been extensively worked by Chinese, but is now shut down. It, however, presents some promise of being developed into a copper mine of importance. At the time I examined this mine, two years ago, the depth of surface soil and the dense
scrub and grass hampered any geological work. In the neighborhood of the mine the country mainly consists of granite and limestone. There are many loose pieces and float stones of a decomposed acid eruptive rock lying around, but I could not, in the time at my disposal, find it in place. Some distance away from the deposit a fine-grained intruding granite was seen, but probably this has not an important bearing on the ore deposit. The main deposit consists of a quartz lode wholly contained in granite, a few hundred feet away from the granite-limestone contact which it follows. Besides this lode, there are bunched or irregular deposits of sulphide ore in the limestone close to the granite. The width of ore in the granite-enclosed lode is about five feet, the ore consisting of chalcopyrite, bornite, and oxidized copper minerals, iron pyrite, galena, and oxidized lead compounds. Silver minerals are probably also present in small amount. The gangue is composed of quartz. The ore contains about 7% copper and 15 to 20 oz. silver per ton. The Chinese worked it as a silver mine, carefully sorting out the argentiferous galena and smelting it in primitive clay furnaces. The irregular bodies of sulphides in the limestone are poorer in copper, averaging about 2%, but richer in silver, averaging about 30 oz. per ton. They contain no gangue and contact minerals are absent.*

Open-hearth steel rails will soon be used exclusively on the Long Island lines of the Pennsylvania railroad, a first order for 900 tons, for 1909 delivery, having been placed with the Bethlehem Steel Co. The change from bessemer to open-hearth rails will not interfere with the usual distribution of Pennsylvania's rail order, as all leading companies make open-hearth rails. Many rail-makers have been putting in open-hearth plants to meet the views of railroads which desired to change from bessemer. It is expected that the rails will cost $2 to $3 per ton more than bessemer. A number of railroads have been experimenting with open-hearth rails for several years with such good results that many engineers believe it only a question of time when every road will more largely use them. This recalls the prophetic statement of the late Alexander Holley that the open-hearth process would live to attend the funeral of the bessemer. It should be noted, however, that the makers of bessemer steel are introducing dry-blast to mitigate the evils of variable quality which moisture in the air occasions.

Contrary to the usual custom in crushing for concentration, stamp-mills are quite extensively employed in Cornwall, England, for reduction of tin ores, the mineral being so finely disseminated as to render this good practice. The ores at the South Crofty mine may be taken as typical, averaging about 25 lb. tin and 12 lb. wolfram per ton, with 0.25% copper and 15% arsenic, the gangue consisting essentially of quartz, feldspar, mica, tourmaline, chlorite, and fluor spar.

*The foregoing description is taken from a letter sent to Mr. W. H. Weed, who sent it to the Editor.
DISTRIBUTION OF THE NATION'S MINERAL WEALTH.

By Geo. Otis Smith, Director.

"The subject eminently fits both the place and the occasion. The city of Pittsburg, rightly termed "the world's industrial wonder," is founded on the mineral resources of not only Pennsylvania but indeed of the whole country, while you members of the American Mining Congress represent the industry that has enabled this nation to realize a rich income from its mineral heritage. Nor is it inappropriate that a representative of the United States Geological Survey should bring to your attention facts relating to the distribution of this mineral wealth. In the 30 years since its organization this Federal bureau has recorded the development of the mineral industry, and to indicate how phenomenal has been this development, I need only cite the fact that during these three decades the mineral production of the nation has increased six-fold.

We should not leave this topic of the 30 years' development without mention of certain notable features in the growth of the mineral industry. In 1880 the non-metallic products constituted 47% of the total mineral production of the country; in 1907 fully 57%. This increase in relative importance of the non-metallic products has not been regular, inasmuch as metals have exhibited a tendency to be more quickly affected by general business conditions, with the result that for the year 1894, for instance, the non-metallic percentage rose to 65%, and again in 1904 to 63 per cent.

The pages since 1880 can also be studied in another manner. Then, in order of value of output, coal stood first, with iron second, followed by gold, silver, petroleum, lime, building stone, copper, lead, and salt. In last year's production, after coal and iron came copper, clay products, petroleum, gold, stone, cement, natural gas, and lead. You will note that in this column of the ten most important mineral products, coal, iron, petroleum, and building stone have maintained their relative positions notwithstanding the six-fold total increase. Copper has advanced from eighth to third place, and gold has dropped from third position to sixth, lead from ninth to tenth, and silver to just behind lead. The newcomers in the 1907 list, as contrasted with that of 1880, are clay products, cement, and natural gas.

The distribution of mineral wealth depends on geologic factors, and different geologic provinces are characterized by deposits of different minerals. Herein lies the value of much of purely geologic study. Thus an important part of the Survey's work through these years has been to keep the country informed as to the occurrence of economic minerals. Not only has the Survey statistician been recording the increasing activity of mine, furnace, and smelter, but the Survey geologist has been mapping and measuring the nation's mineral deposits and investigating the possibilities of new discoveries of the mineral fuels and ores. In the last few weeks the result of this great inventory which it has taken years to make has been brought together in the report submitted to the National Conservation Commission, and it is the existence of these quantitative data that enables me to discuss this important subject at all adequately.

The facts of the distribution of mineral wealth are of practical value because of the vital connection between such geographic distribution and the development of manufactures and commerce. I give precedence to manufactures because this industry, rather than commerce, should first feel the creative influence of mineral wealth. The metallurgical, clay-working, structural, and chemical industries constitute the web and woof of industrial prosperity, and to a large degree it is only the disregard of the principles of political economy that permits the export of raw material beyond the boundaries of State or nation. Free trade among the States of this union has developed inter-state and internal commerce on a grand scale, but this phenomenal national development should not blind the people of the individual States to the advantage of local utilization of their own mineral resources. As an illustration of this, the new industrial South is possible because the South has always possessed mineral wealth. With these Southern States mining nearly 7% of the iron ore of the United States, and over 21% of the coal, it is simply obedience to natural laws that the Southern furnaces should produce 10% of the pig-iron of the country. Economic laws must be recognized, and the fact of distribution and production—of supply and consumption—must be in mind before we can at all comprehend the interrelation existing between all branches of the mineral industry to plan intelligently for its future development.

Let me cite a few characteristics of the distribution of our mineral wealth. In the first place, the widespread distribution of raw material makes possible an industrial nation in which every State and Territory has some share in the mineral production. Last year only three States had a mineral output valued at less than a million dollars, and 12 States had a production valued at over fifty million dollars each.

Again, no State or region appears to have a monopoly of the mineral industry. While "progressive Pennsylvania," with its total mineral product nearly one third that of the whole country, leads in coal, cement, stone, and natural gas by large margins, another State, Minnesota, leads in iron ore; another, Arizona, in copper; another, Ohio, in clay products; Oklahoma in petroleum, Colorado in both gold and silver, and Missouri in both lead and zinc. Furthermore, these centres of production are ever shifting.

For instance, in 1900 the primary in quantity of petroleum produced passed from Ohio to California, thence to Oklahoma, and within a year Montana in copper production has given place to Arizona; in lead, Idaho to Missouri, and in silver, Montana to Colorado. It is evident that we cannot prophesy future progress of the industry unless we can determine the centres of the mineral reserves, for it will be toward these centres that the industry will tend.
PREVENTION OF MINING ACCIDENTS

Soon after the adjournment of the last session of the American Mining Congress a series of unusually disastrous explosions in coal mines of West Virginia, Alabama, and Pennsylvania called the attention of the general public as well as of the mining fraternity to the subject of accidents as it has never been called before. Consequently, much attention has been given to the subject during the past year both in the public and the technical press, and a large amount of experiential work has been carried on by individuals and by corporations since the close of the last session Congress. These accidents probably also hastened the establishment of a Government Testing Station, and assisted in the securing of an appropriation for the investigation of mine accidents in the United States by the Technological Branch of the United States Geological Survey.

As a result of the widespread publicity given to the subject of accidents through the public and the technical press, and through various mining organizations, together with the organization of a Testing Station and the development of a distinct organization to investigate accidents by the Technological Branch of the Geological Survey, it was unnecessary for your committee to attempt to carry on work along the lines for which it was originally appointed, as the work would have paralleled that already being done by others.

It being entirely probable that this work, both public and private, will continue, we recommend the discharge of the committee, and in so doing would make the following comments:

We believe that prevention of accidents depends upon (1) a realization of the relative importance of the various known causes to which accidents can be attributed, so that suitable preventive measures can be adopted to minimize as far as possible the accidents due to these known causes. Under normal conditions in coal mining from 50 to 60% of the accidents are due to falls of rock and coal, about 16% to the explosions of gas and dust, and an almost equal number, or 14%, to mine-cars. Owing to the large number killed at one time by explosions, this cause of accident has attracted more than its due share of attention, and while not wishing to minimize in any way the importance of the attempts made to lessen these dangers due to dust and gas, we most earnestly urge that more attention be given to the great cause of mine fatalities which is everywhere present, namely, falls of slate, coal, and rock. (2) The scientific investigation of the problems connected with mining both theoretical and practical, and which are now only partly understood, should continue. The most important of these are probably the choice, handling, and use of explosives; problems connected with explosive gases and dust in coal mines; better supervision and more careful timbering to prevent the great loss of life and the accidents due to falls of rock and coal.

The training of vast numbers of immigrants from southeastern Europe who are so rapidly replacing the former mining population and who come to us with no knowledge of mining is one of the serious problems affecting the accident conditions in this country.

The conditions under which American mines are operated must be kept distinctly in mind, and the vast differences between European and American conditions must be remembered in comparing the statistics of accidents abroad and in American mines.

We believe that the mine laws now on the statute books, if enforced and respected by employer and employee alike, are sufficient in many cases to greatly reduce the number of accidents. There are no doubt instances where the laws can be modified to advantage to conform to present knowledge and conditions, but these modifications should be made by persons familiar with the conditions under which American mines must be operated, and who also understand the theory and practice of such new forces as electricity, compressed air, etc., that now play so important and necessary a part in mining. A greater uniformity in the mine laws of the different States where the conditions are similar would be advantageous.

We believe that experience in one State should be allowed full credit in another for a person applying for a certificate as mine foreman, manager, etc., provided he can satisfy the requirements of examination as provided for in the State in which the application is made.

We would also call attention to the fact that several persons are injured for every one killed, and we believe that a useful work can be carried on in assisting those injured about the mines through the use of intelligent first-aid measures. The various devices used in case of rescue work after an accident will undoubtedly be tested at the Government Testing Station, as has been done abroad, and as the result of these tests become known it is to be expected that more adequate means for rescue in case of explosion, fire, etc., will be installed at many of the mines. The circumstances requiring such apparatus are, however, fortunately comparatively rare, while every day men are being injured more or less severely about the mines. The rendering of efficient first aid to such men while awaiting the arrival of a physician may mean in many cases the saving of life or the prevention of permanent deformity. We would therefore especially call attention to the very thorough first-aid organizations which have been developed in the anthracite mines of Pennsylvania.

Purification of mercury, according to Bettel, may be accomplished by using a 2% solution of KCN with addition at intervals of a little NaOH. The ordinary impurities are thus completely removed from Hg. While the base metals are being dissolved (which in a case cited required about four days) but little gold was removed. After that the removal of gold was fairly rapid, diminishing, of course, in speed as the proportion of gold became less.
Lea-Degen Centrifugal Pump.

The general design of the Lea-Degen pump, made by the Lea Equipment Co., of New York, is shown in the drawing. It consists essentially of two shrouded runners, or pump wheels, mounted on the same shaft in a frame, communicating with each other. It is designed so that the water is drawn from the source of supply and put under pressure by the first wheel, and then delivered to the suction chamber of the second wheel. The second wheel then imparts to the water the same amount of energy it receives from the first wheel, thereby increasing the pressure, and then delivers the water into a spiral discharge conduit terminating in a diverging nozzle connecting with the main pipe. The dimensions of a pump recently tested were: diameter of suction pipe, 10 in.; diameter of discharge pipe, 10 in.; outline diameter of each wheel, 24 in.; number of blades, eight.

The special features of the pump which represent patented advantages are: (1) The case is divided through its horizontal diameter by bolted flanges so that its top half can be quickly freed, and lifted off, without disturbing either suction or discharge connections, thereby affording easy access to the internal parts of all the stages at once. (2) By means of bolted circumferential divisions of the case, provision is made for either using the suction and discharge end of a case together as a single-stage pump, or for adding as many intermediate sections as may be necessary to afford any desired pressure at any fixed speed. Additional stages can therefore be installed after a pump has been in operation without wasting any parts of the existing case. (3) A special arrangement of double cup-leather packing is used for both the suction and discharge ends and for the intermediate sections. The cup leathers are held against a flat collar, on extended pump-wheel sleeves, in such a manner that the leathers can follow up as they or the collars are worn, or the shaft may be shifted at will in either direction, with the leathers following, without changing the location of the leather with relation to the shaft collar, thus making a practically water-tight joint at all times. A spiral spring is used, between each pair of cup leathers, to ensure their seating against the collars before pressure is put on the pump. Provision is made for setting out the leather packing on the suction end of the shaft by the water pressure of the high side of the pump. (4) On the outside of the main bearings, at each end, is placed a ball thrust-bearing, with adjusting collars, for shifting the shaft endways to balance the end thrusts of the pump-runners. The balancing is accomplished by means of a variation in the width of water-space, on both sides of the wheels between the rim of the wheel and the case. Experiment showed that as the wheel was moved laterally in the case, the pressure between the wheel and the case increased on the side where the clearance was greatest, and was reduced on the opposite side.

The pump tested was driven by a General Electric direct-current multi-polar dynamo of 335 amperes and 220 volts used as a motor, and direct-connected to the pump-shaft. It was arranged to lift water by suction, about 7 ft., from a well, and to deliver it through a 10-in. throttle-valve to a 6½-in. bell-shaped nozzle, to a weir-tank, which was about 25 ft. long by 10 ft. wide and 10 ft. deep, whence the water flowed through a rectangular notch 5.0 ft. wide in a 1½-ft. bevelled iron plate set in the middle of the end of the tank about 7 ft. above the bottom. A pilot tube was applied under the nozzle, and its indications used as a means of quickly adjusting the discharge of pump to the several amounts of flow necessary for the tests. The amount of water flowing was calculated from the weir heights by the Francis formula.

The weir heights were taken with a hook-gauge in a barrel communicating with the tank by an inch pipe hav- ing an open end square with the flow of water at a point 13 ft. back of the notch. The surface of the water approaching the weir was made perfectly smooth by means of a gridded lattice 6 ft. from the discharge nozzle, and dam-boards set by trial. The zero of the hook-gauge was determined daily with a straight-edge, and checked by a surveyor’s level. Readings of the gauge could be easily made to 1⁄10 of an inch. The leakage of the weir was frequently determined. It remained practically constant at 18 gal. per minute, which was added to the quantity calculated by the weir formula. The total lift of the pump was determined by adding the vacuum shown by mercury gauge to the pressure above the atmosphere shown, the pipe diameter being the same at both points.

The pump was designed by Mr. Degen for practically equal efficiency for the range of speed between 400 and 600 rev. per min. Therefore an efficiency test was made at 400, 500, and 600 revolutions, respectively.

No data were recorded at a speed varying more than two revolutions from the assigned speed, a skilled assistant devoting his attention to this point. After the gallow's lift curves were secured, the pump was disconnected from the motor, and the power of the water absorbed by a prone brake over the same range of speeds applied to drive the motor during the pump tests. From these curves the horse-power corresponding to the watts applied to drive the motor during the pump tests was determined and taken as the horse-power to drive the pump.

The prone brake was of the two-seal-circular, solid-block type, applied to a 28-in. pulley, with 6-ft. lever-arm acting on a knife-edge on tested platform scales. It was carefully balanced with its pulley by balancing the whole combination, with a mandril through the pulley, on straight-edges. A copious stream of water applied to a nipple in the top block, through a long vertical flexible hose, and a hand-tightened wheel, with a leveraged to 100 to 1, enabled the highest loads to be maintained indefinitely with a steady equipoise of the scale-beam. The electrical readings were made from a Weston instrument from the laboratory of the Stevens Institute.

The tests, which were made by J. E. Denham, Professor of Engineering Practice at the Stevens Institute of Technology, Hoboken, N. J., show that the pump afforded the following results under conditions of maximum efficiency:

<table>

</tbody>
</table>

In round numbers, therefore, the capacity at maximum efficiency is directly proportional to the revolutions, and the lift, or head, is proportional to the square of the revolutions. At each speed the efficiency averaged more than 76% over a range of 600 gal. capacity for the lower two speeds, and 800 gal. at the higher speed, the head remaining nearly constant.

To test the effect on the end thrust of altering the clearance, pipes were tapped into the case, on either side of the high wheel and connected to the two ends of a U mercury tube. With the shaft in the position in which it had been adjusted for the test, there was no difference of pressure shown by the mercury.
